Gold-Catalyzed Intermolecular Annulation to Access Heterocyclic Compounds

Oral examination: November 10th, 2017

Gutachter: Prof. Dr. A. Stephen K. Hashmi
Prof. Dr. UweH. F. Bunz
Eidesstattliche Versicherung gemäß § 8 der Promotionsordnung
der Naturwissenschaftlich-Mathematischen Gesamtfakultät
der Universität Heidelberg

1. Bei der eingereichten Dissertation zu dem Thema
   Gold-Catalyzed Intermolecular Annulation to Access Heterocyclic Compounds
   handelt es sich um meine eigenständig erbrachte Leistung.
2. Ich habe nur die angegebenen Quellen und Hilfsmittel benutzt und mich keiner
   unzulässigen Hilfe Dritter bedient. Insbesondere habe ich wörtlich oder sinngemäß
   aus anderen Werken übernommene Inhalte als solche kenntlich gemacht.
3. Die Arbeit oder Teile davon habe ich wie folgt/bislang nicht1) an einer Hochschule
   des In- oder Auslands als Bestandteil einer Prüfungs- oder Qualifikationsleistung
   vorgelegt.
   Titel der Arbeit:_______________________________________________________
   ___________________________________________________________________
   Hochschule und Jahr:__________________________________________________
   Art der Prüfungs- oder Qualifikationsleistung:_____________________________
5. Die Bedeutung der eidesstattlichen Versicherung und die strafrechtlichen Folgen
   einer unrichtigen oder unvollständigen eidesstattlichen Versicherung sind mir bekannt.
   Ich versichere an Eides statt, dass ich nach bestem Wissen die reine Wahrheit erklärt
   und nichts verschwiegen habe.
   ____________________________ ______________________________
   Ort und Datum           Unterschrift
1) Nicht Zutreffendes streichen. Bei Bejahung sind anzugeben: der Titel der andernorts
   vorgelegten
   Arbeit, die Hochschule, das Jahr der Vorlage und die Art der Prüfungs- oder
   Qualifikationsleistung.
Acknowledgements

I enjoyed the fantastic three years in Heidelberg. Not only did I like the beautiful scenery but also the friendly and kind people. At the end of this wonderful journey, I must appreciate all people who gave a hand in my research and favourably impressed on my life.

First and foremost, I would like to express the deepest gratitude to my supervisor, Prof. Dr. A. Stephen K. Hashmi, Vice-President Research and Structure of Heidelberg University. He has much enthusiasm for chemistry and encourages me greatly. I am very grateful for his constant guidance and support in profession and personality.

I also thank Prof. Dr. Uwe Bunz for his willingness to be my second Gutachter without any hesitation.

By this opportunity, I acknowledge the “China Scholarship Council” fellowship for affording the financial support to undertake my PhD study.

My thank goes out to Dr. Matthias Rudolph. I really appreciate his inspiring suggestion for my experiment and the contribution on the revision of my papers. I also congratulate him to be the father of two babys!

I would like to thank Herr Alexander Flatow for his support in chemistry supplies and equipment maintenance. A big thank you to Frau Petra Krämer for her kindness in helping me with the analytical measurements. I am also grateful to Frau Christiane Eckert for her assistance in the letter delivery and management.

Many thanks to all Chinese friends in this group. My special thanks to Dr. Jin Xie, he helped me overcome difficulties and join the new family. I also thank to Tuo Zhang, Long Huang, Fei Chen, Jian Li, Jintao Yu, Bing Tian, Xinlong Song, Zhongyi Zeng, Qian Wang, Ximei Zhao, Xianhai Tian, Yangyang Yang, Yufeng Wu, Lumin Zhang and Xiaojia Si for the happiness we experienced and delicious foods we shared.
I would like to appreciate all the members of Hashmi’s group whom I worked with and have not already mentioned, they are Marcel Wieteck, Pascal Nösel, Tobias Lauterbach, Hui-Ling Sung, Verena Göker, Daniel Pflästerer, Max Hansmann, Sabrina Gatzweiler, Anna Zeiler, Eva Rettenmeier, Janina Bucher, Svetlana Tsupova, Thomas Wurm, Assunta De Nisi, David Zahner, Florian Mulks, Poorya Zargaran, Jürgen Schulmeister, Vanessa Weingand, Danilo Machado Lustosa, Marc Zimmer, Jasmin Schießl, Alexander Ahrens, Sebastian Arndt, Tapas Adak, Kohei Sekine, Sina Witzel, Christoph Hendrich, Svenja Taschinski, Daniel Eppel, Melanie Pearsall.

I also appreciate all people from the organic chemistry institute who offered analytical and technical help, including HRMS, X-ray, NMR, glass work and chemical store.

Finally, I am really grateful to my parents, my wife and my whole family for their understanding, support and love all the time.

Abstract

In chapter 2, the gold-catalyzed C-H annulation of anthranil derivatives with alkynes offers a facile, flexible, and atom-economical one-step route to unprotected 7-acylindoles. An intermediate a-imino gold carbene, generated by an intermolecular reaction, promotes ortho-aryl C-H functionalization to afford the target products. The transformation proceeds with a broad range of substrates under mild conditions. Moreover, the obtained functionalized indole products represent a versatile platform for the construction of diverse indolyl frameworks.

In chapter 3, a gold-catalyzed cascade annulation of propargylic silyl ethers with anthranils proceeds through a sequential ring opening/1,2-H-shift/protodeauration/Mukaiyama aldol cyclization. This method offers a regiospecific and modular access to 2-aminoquinolines and other quinoline derivatives under mild conditions and with a broad functional-group tolerance. The conversion is possible on a gram scale, which underlines the synthetic practicability of this methodology. The versatility of the obtained scaffold has been demonstrated by useful postfunctionalization.

In chapter 4, gold and platinum-catalyzed counteranion-directed divergent [4+2]...
annulations have been described, enabling the convergent assembly of densely substituted quinoxaline and quinoxaline $N$-oxide from benzofurazans and ynamides. A broad scope of functional groups was well tolerated, delivering high regioselectivity. The quinoxaline $N$-oxides were suitable for the further C-H functionalization. Mechanism studies suggested the counteranion-tuned distinct cyclization pathways toward the corresponding product.

In chapter 5, the gold-catalyzed oxidative [2+2+1] annulation of two molecules of ynamide with 2, 3-quinoxaline $N$-oxide, enables the facile and convergent assembly of fully-substituted symmetric and unsymmetric furan frameworks. A wide range of functional groups is well compatible due to the mild condition. The strategy works also for the intramolecular macrocyclization of di-ynamides for the synthesis of macrocyclic furan derivatives.
Kurzzusammenfassung

Chapter 1: General Introduction

1.1 Gold Carbene Species in Homogeneous Gold Catalysis

Gold was recognized as currency decoration thousands of years ago. However, the catalytic activity of gold compounds has been ignored until the last century. During the past decades, homogeneous gold catalysis has been booming and afforded various flexible, versatile and atom-economic strategies for the construction of complex molecular frameworks. Due to the pronounced carbophilicity of gold complexes, enormous efforts in this field referred to gold-catalyzed alkyne activation and transformation, with high functional group tolerance and mild reaction condition. In these reaction mechanisms, gold carbenes are often involved and considered as a key electrophilic intermediate despite still continuing debates on their structure and nature.

The first reaction involving gold carbene intermediates was the furan-yne transformation for Hashmi phenol synthesis. Subsequently, the nature of gold carbenoid, carbene versus carbocation, was fully discussed by Hashmi, Fürstners and Echavarren et al. A bonding model for gold carbenes was described by Toste’s group in 2009. The gold core can accept two pairs of electrons from the ligand and carbene respectively to produce a three-center four-electron \( \sigma \)-hyperbond. Meanwhile, two \( \pi \)-backdonations are formed by electrons transfer from two filled 5d orbitals on gold to empty \( \pi^* \)-antibonding orbitals of the ligand and the carbene. The most common approaches to gold carbenes are summarized in Scheme 1, including: a) 1, 2-acyloxy migration of propargylic carboxylates; b) the decomposition of diazo compounds; c) the direct alkyne oxidation and amination; d) ring-opening of cyclopropenes; e) intramolecular cycloisomerization of enynes. The bonding of some gold carbenes has been investigated in great detail by DFT computations.

In this chapter, gold carbenes resulting from alkyne amination and oxidation are highlighted (Scheme 1, c). A range of gold carbene-triggered intramolecular and intermolecular cyclizations to access heterocyclic compounds will be reviewed.
1.2 α-Imino Gold Carbene-Mediated Syntheses of Heterocyclic Compounds

The first report on the generation of an α-imino gold carbene by the intramolecular acetylenic Schmidt reaction of alkynes with an tethered azide was developed by Toste and co-workers (Scheme 2, a).[11] In this work, the α-imino gold carbene was invoked by the intramolecular nucleophilic azide addition to an alkyne followed by losing nitrogen. Through 1,2-hydride/alkyl migration pyrrole products were furnished. Inspired by this reaction, Zhang and Gagosa’s group reported indole and 3-indolinone synthesis via analogous α-imino gold carbene intermediates, in which the gold carbene was trapped by aryl nucleophiles or allyl alcohols (Scheme 2, b).[12] Further, the strategy was successfully applied to the preparation of bicyclic imidazaole[13] and quinoline[14] derivatives.
Instead of azides, Gagosz et al. found 2H-azirines as alternative nitrene precursor to access α-imino gold carbene via intramolecular cyclization followed by strained ring-opening (Scheme 3). A broad scope of functionalized pyridines was obtained in excellent yields.

Compared with intramolecular cyclizations toward heterocyclic compounds, the intermolecular formal cycloaddition for heterocycle construction is more flexible and
versatile without tedious steps in the synthesis of substrates. In 2011, by incorporation of ynamides into the gold-catalyzed nitrene transfer, Davies’s group reported the gold-catalyzed [3+2] annulation of ynamides with iminopyridium yields densely substituted oxazoles \(^{[16a]}\) with the gold(III) complex \(^{[16b]}\) as catalyst (Scheme 4, a). As well as aryl substituents, alkyl substituted \((R^1)\) ynamides were also suitable for the reaction without \(\alpha\)-H elimination products, which suggested that the C-O bond formation might be faster than N-N bond cleavage. Subsequently, the methodology was expanded to the synthesis of fused imidazodiazines and imidazopyridines, in which electron-rich internal alkynes reacted smoothly as well as ynamids (Scheme 4, b). \(^{[17]}\)

\[ \begin{align*}
\text{Scheme 4.} & \quad \alpha\text{-Imino gold carbenes generated via intermolecular nitrene transfer.}
\end{align*} \]

In 2015, Huang and Liu’s group exploited the intermolecular [3+2] annulation of ynamides with 2\(H\)-azirines, enabling the atom-economic synthesis of various 2-aminopyrroles (Scheme 5, a). \(^{[18]}\) Furthermore, the nucleophilic vinyl azide turned out to be a well suitable equivalent of 2\(H\)-azirines (Scheme 5, b). \(^{[19]}\)
Scheme 5. 2H-azirines as a nitrene equivalent.

In the same year, Ye’s group published an alternative intermolecular [3+2] annulation towards 2-aminopyrroles taking advantage of isoxazoles as a nitrene equivalent (Scheme 6).\textsuperscript{[20]} The $\alpha$-imino gold carbene was produced by gold-promoted N-O bond cleavage and then underwent a $4\pi$-electrocyclization/deauration processes. The structure of the final product was depended on the $R_3$-substituents. 3-Acyl pyrroles were gained followed by 1, 3 H-shift, while water-assisted deacylated products were observed in the case of alkyl and aryl substituents.

Scheme 6. Isoxazoles as a nitrene equivalent.
In 2016, another intermolecular nitrene transfer reagent, dioxazole, was described by Liu’s group. The α-imino gold carbene might be produced via a tandem N-O bond cleavage/acetone releasing process. The gold-catalyzed intermolecular formal [3+2] cycloaddition provided a novel protocol to oxazole derivatives under mild conditions (Scheme 7, a). Moreover, an intramolecular cascade cyclization was conducted to demonstrate the generation of an α-imino gold carbene intermediate (Scheme 7, b).

Scheme 7. Dioxazoles as a nitrene equivalent.

Ye and co-workers reported the first instance on gold-catalyzed intermolecular transformation of ynamides with benzyl azides. Remarkably, the kind of benzyl azides has a crucial influence on final products and yields. Generally, treatment of 3-bromobenzyl azide and N-aryl substituted ynamides led to 2-aminooindoles in good to excellent yields even at room temperature, whereas Boc-protected indolyl azides offered a [4+2] annulation toward 3-amino-β-carbolines proceeded by AgOAc oxidation (Scheme 8). Subsequently, the benzyl azide was employed to the reaction with 3-en-1-ynamides to initiate aza-Nazarov cyclization for the synthesis of 2-aminopyrroles (Scheme 9).
Besides of ynamides, Ballesteros et al. reported an α-imino gold carbene-mediated three component cascade reaction involving common terminal alkynes (Scheme 10).[24] A highly nucleophilic dipolar triazapentalene derivative was in-situ generated via gold-aided 5-endo-dig cyclization of the propargylic benzotriazole and enabled the reaction with gold-activated terminal alkyne to provide α-imino gold carbene intermediates. Then, the gold carbene could be easily captured by the external nitrile following an intramolecular cyclization. Both pyrazole and imidazoles were formed in one-pot.
Scheme 10. Gold-catalyzed three component cascade reaction of alkyne, nitrile and propargylic benzotriazole.

1.3 α-Oxo Gold Carbene-Mediated Syntheses of Cyclic Compounds

In 2008, Hashmi and Liu et al. independently reported that an internal epoxide can oxidize an alkyne leading to an α-oxo gold carbene, which is involved by in a further cyclization with the nascent C–C double bond. (Scheme 11, a).\textsuperscript{[25]} Subsequently, Liu’s group disclosed a formal [2+2+1] cycloaddition of a nitroso species, external alkenes and α-oxo gold carbenoids, which results from intramolecular oxidation \textit{via} nitro groups, delivering bridged products with excellent diastereoselectivity. (Scheme 11, b).\textsuperscript{[26]}
In 2010, Zhang’s group reported the intermolecular generation of α-oxo gold carbenes via the reaction of alkynes with pyridine N-oxides (Scheme 12). The resulting gold carbene could be trapped by the tethered O- and N-nucleophile to give a variety of functionalized heterocyclic compounds. Especially, highly strained 4-member rings were afforded in good to excellent yields.

Scheme 11. Intramolecular generation of a presumed α-oxo gold carbene.

Scheme 12. Intramolecular trapping of α-oxo gold carbene by heteroatom-nucleophiles

In 2013, Hashmi and co-workers described the gold-catalyzed oxidative cyclization of diynes (Scheme 13). The α-oxo gold carbene accessed by alkyne oxidation was
transferred across the adjacent alkyne undergoing a 1, 5-carbene shift. The resulting vinyl gold carbene could be quenched by 1, 2-alkyl migration. Moreover, the oxidation of the vinyl carbene intermediate proved the 1, 5-carbene shift process.

Scheme 13. α-Oxo gold carbene-initiated intramolecular 1, 5-carbene shift.

Lately, Zhang et al successfully achieved the intramolecular cyclopropanation of an alkene with an α-oxo gold carbene.\(^{[29]}\) Taking advantage of a newly designed chiral \(P, N\)-bidentate ligand enabled the gold-catalyzed enantioselective synthesis of polycyclic cyclopropane derivatives (Scheme 14).

Due to the high electrophilicity, $\alpha$-oxo gold carbenes can also induce a $sp^2$-C-H insertion. Zhang’s group reported the intramolecular attack of an electron-rich benzene onto a presumed gold carbene in the aryl propargyl ether oxidation (Scheme 15). A large array of valuable chroman-3-ones was gained in moderate to good yields with sterically hindered ligands on the gold catalyst.

![Scheme 15](image)

**Scheme 15.** Intramolecular trapping of $\alpha$-oxo gold carbenes by electron-rich arenes.

Recently, a notable progress in $\alpha$-oxo gold carbene-triggered the unactivated $sp^3$-C-H bond functionalization was disclosed by Zhang’s group. Ynones were used as substrates to generate $\beta$-diketone-$\alpha$-gold carbene species are capable of common $sp^3$-C-H insertion to offer versatile spiro-, bridged and fused cyclopentanones (Scheme 16). The Thorpe-Ingold effect on substrate conformation is a key factor for cyclized efficiency.

![Scheme 16](image)

**Scheme 16.** Intramolecular trapping of $\alpha$-oxo gold carbene by unactivated $sp^3$ C-H.

Compared to the myriad of intramolecular trapping pathways, intermolecular cycloadditions of $\alpha$-oxo gold carbenes is still limited to the cascade reaction with nitriles and amides. In 2011, Zhang’s group reported the first instance on
intermolecular trapping of α-oxo gold carbenes by nitrile solvents, enabling a convergent [2+2+1] synthesis of 2, 5-disubstituted oxazoles from terminal alkynes, nitriles and quinoline N-oxides (Scheme 17, a). Owing to the high electrophilicity, gold carbenes are easily over-oxidized by N-oxides, which disable the subsequent reaction. In 2012, a bidentate ligand was developed to temper the reactivity of terminal α-oxo gold carbenes suitable for trapping by stoichiometric external amides. A [3+2] annulation was furnished to access diverse 2, 4-disubstituted oxazoles (Scheme 17, b).

Scheme 17. Intermolecular trapping of α-oxo gold carbene by nitriles and amides.

1.4 Research Objectives and Thesis Outline

The research projects exhibited in this thesis focus on gold carbene-mediated intermolecular annulations toward various heterocyclic compounds, which are difficult to prepare by conventional methods. Novel and atom-economy approaches to α-imino gold carbenes are also described. Moreover, platinum carbenes will be discussed under some special conditions.

In chapter 2, a gold-catalyzed formal [3+2] cycloaddition of alkynes with anthranils is
presented to offer synthetically valuable $N$-unprotected 7-acylindoles. Chapter 3 describes a gold-catalyzed [4+2] annulation towards the 2-aminoquinoline framework via the umpolung of a gold carbene carbon. Chapter 4 discloses a counteranion-controlled gold and platinum-catalyzed divergent [4+2] annulation of ynamides with benzofurazans to selectively access quinoxaline $N$-oxides and quinoxalines. In chapter 5, the $\alpha$-oxo gold carbene-triggered oxidative [2+2+1] approach to full-substituted furans and macrocyclic furan derivates is developed by taking advantage of the amphoteric character of ynamides. 2, 3-dichloroquinoxaline $N$-oxide is found to suit the cascade reaction.

Chapter 2: Gold-Catalyzed C-H Annulation of Anthranils with Alkynes: a Facile, Flexible and Atom-Economical Synthesis of N-unprotected 7-Acyl Indoles

2.1 Introduction

Indoles have attracted immense attention owing to their ubiquitous presence in natural products, drug molecular and materials.\textsuperscript{[1]} Among indoles, 7-acylindoles serve not only as a class of bioactive molecules (Scheme 1), but also as key building blocks with orthogonal chemical reactivity.\textsuperscript{[2]} However, conventional methodologies,\textsuperscript{[3]} such as the Fischer, Larock and Bartoli syntheses, usually show low functional group tolerance and difficulties in installing aldehydes and ketones make it a challenge to construct 7-acylindoles. Hence, the development of a general synthetic strategy for the efficient construction of a diversified scaffold of 7-acylindole would be highly desirable.

Scheme 1. Selected bioactive compounds based on 7-acylindoles

In recent years, transition metal-catalyzed synthesis of functional indoles has experienced significant development.\textsuperscript{[11,4]} Gold catalysis\textsuperscript{[5,6,7e]} especially has had a strong impact on this field of synthetic chemistry. For example, gold-catalyzed intramolecular annulation\textsuperscript{[5]} of 2-alkynyl arylazides has afforded an efficient access to
indolyl$^{[6b,d]}$ and pseudoindoxyl$^{[6a,c]}$ skeletons, based on α-imino gold carbenoids as electrophilic key intermediates. However, the access towards α-imino gold carbenoids by intramolecular nitrene transfer can limit the generality and flexibility of the obtained products. Regarding this drawback, an intermolecular approach for the generation of an imino gold carbene species en route to functionalized heterocyclic compounds would represent an attractive strategy. In line with this principle, Davies et al. and Ye et al. successfully accomplished gold-catalyzed intermolecular cycloaddition for the preparation of polysubstituted oxazoles$^{[7a, b]}$ and pyrroles$^{[7c]}$. Very recently, the gold-catalyzed intermolecular transformation of benzyl azides with ynamides was also reported by Ye’s group.$^{[7d]}$ However, the α-imino gold carbenes that are produced through the intermolecular approach have so far been limited to polarized alkynes. Inspired by these reports and in continuation of our work on indole chemistry,$^{[8]}$ we envisioned that a gold-catalyzed intermolecular transformation of anthranil with alkynes could produce α-imino gold carbene intermediates. Based on the high electrophilicity of the α-imino gold carbenoid, an intramolecular ortho-aryl C-H insertion could then afford the desired 7-formyl indoles (Scheme 2). Herein, we report our results on the unprecedented gold-catalyzed C-H annulation of anthranils with alkynes under mild reaction condition. Remarkably, the reaction also proceeds smoothly with ynamides, non-polarized alkynes, and non-terminal alkynes. The process enables a facile, flexible and atom-economical synthesis of 7-acylindolyl frameworks.

Scheme 2. Planned gold-catalyzed annulation of anthranils with alkynes.
2.2 Results and Discussion

2.2.1 Optimization of the Reaction Conditions

Initially, we conducted a screening of the reaction conditions with ynamide 1a, since such substrates usually possess high reactivity in gold catalyzed reaction as a result of their electronic properties\(^{[7a-d,9]}\) (Table 1). Treatment of ynamide 1a and anthranil 2a with Ph\(_3\)PAuCl/AgNTf\(_2\) at 0 °C provided the expected product 3a in 36 % yield (entry 1). Among the screened gold catalysts, the catalyst with an NHC ligand (entry 6) showed higher activity than those with phosphane and phosphite ligands (entries 2-4). AuBr\(_3\) was less efficient as well (entry 5). The yield increased to 84 % upon decreasing the reaction temperature to -20 °C (entry 7). Further, improvement was achieved by taking advantage of different silver salts (entry 8, 9) and solvents (entry 10-17). Finally, up to 90 % yield of 3a was gained by employing 5 mol% IPrAuCl/AgNTf\(_2\) as catalyst in PhCF\(_3\) at -20 °C (entry 11). The control experiment without catalyst showed no reaction even at room temperature (entry 18).

[^a]: Reaction conditions: 1a (0.3 mmol), 1b (0.2 mmol); a solution (1 ml) of 1a was added over 3 mins to a solution (1 ml) of 1b and the catalyst at the according temperature, reaction time 1 h.  
[^b]: Measured by ¹H NMR using 4-(dimethylamino)benzaldehyde as the internal standard.  
[^c]: Ar = 2, 4-di-tert-butylphenyl.  
[^d]: Isolated yield.

### 2.2.2 Scope and Limitation

With the optimized condition in hand, the scope of the reaction was explored (Table 2). Ynamides reacted with excellent to moderate yields (3a-3j). A broad set of substitutents at the ynamide nitrogen atom turned out to be compatible. 7-Formyl indole 3e which was prepared from N-(2-bromophenyl) ynamide in good yield, is a potential precursor for the synthesis of 1,2-fused indoles according to a method from Perumal’s group[^4g]. Among the tested protecting groups on the ynamides, besides tosyl and mesyl, the oxazolidinone-derived ynamide also underwent the annulation to afford the product 3j in moderate yield. Non-terminal ynamides were also investigated and the targeted product (3k) was prepared from phenyl-substituted ynamide in good yield, the alkyl-substituted ynamide afforded the H elimination product 3l’ rather than 3l. Various substituted anthranils were employed for the synthesis of diversified 7-acylindoles (3m-3y). Owing to the mild reaction conditions,
a large array of functional groups, including ester (3n), acetal (3o), chloride 3p, bromide (3q, 3r), alkene (3v) and α, β-unsaturated ketones (3w-3y) were all tolerated, which enormously enhances the range of the obtained substrates. The reaction of anthranils with electron-donating groups usually proceeded with higher yields, which suggests an electrophilic aromatic substitution mechanism. For a structural confirmation of the 7-acylindolyl framework, a single crystal X-ray structure analysis\(^{[10]}\) of 3q was performed (Figure 1).

---

**Figure 1.** Solid-state molecular structure of 3q.

The transformation was not only limited to ynamides. The reaction of anthranil and aryl alkynyl ether 4a under the standard reaction condition furnished 2-oxyl product 5a in 63 % yield (Scheme 3, Step 1). 7-Formyl oxindole 5a’, a promising novel antioxidant[11], was easily gained by the hydrolysis of 5a under acid condition.
Scheme 3. The reaction of anthranil with aryl alkynyl ether

To extend the scope of substrates further, the non-polarized alkynes were used as well. However, owing to their decreased reactivity, the reaction did not work under the standard condition. But by raising the temperature and extending the reaction time, the yield of the expected product could be gradually increased.\textsuperscript{[12]} By the addition of 10 mol% MsOH, which might facilitate the deauration process and by using an excess of alkyne (MsOH alone is not catalytically active) enabled a more efficient conversion rate of anthranil, delivering the products in moderate yields. Under the adjusted conditions, both alkyl and aryl alkynes were suitable for the construction of C2-functionalized and C2, C3-diarylated products (Table 3, 7a-7i). The 7-substituted indole 7j, which is a key precursor for synthesizing pyrrolquinolone derivatives,\textsuperscript{[13]} could facilely be prepared despite the conjugated double bond.

[a] Reaction conditions: 6 (0.8 mmol) and 2 (0.2 mmol) were heated for 4 h at 65 °C in 2 ml PhCF₃. [b] Isolated yields.

Scheme 4. Conversion of an unsymmetrical alkyne.

Finally, an unsymmetrically alkyl/aryl-substituted alkyne was used. In this case, a low yield of 2-alkyl-3-aryl indol 7k was obtained (assigned by NOE) and no other indole isomer was formed (Scheme 4). The low yield might result from a competing hyride-shift pathway if the carbenoid is formed next to the alkyl tether (similar to the formation of 3l').

2.2.3 Further Derivatisation

Owing to the presence of both electrophilic and nucleophilic sites, 7-formyl indoles have been utilized as flexible scaffolds for the syntheses of 1, 7-fused indoles, most of which exhibit significant biological activity. While numerous studies have focused on the reactions of indoles with electrophiles, we turned our attention on nucleophilic transformations of 7-acyl indoles. For instance, the reduction of 3g afforded the 7-alkylated product 3g' and the unprotected 7-alkynyl indole 3g'' could be obtained easily in excellent yield through Seyferth-Gilbert homologation (Scheme 5).
2.3 Summary

In summary, we described a novel, short, and atom-economical synthesis of 7-acyl indoles through gold-catalyzed C-H annulation of anthranils with alkynes. The substrate scope is remarkably broad and the benign reaction conditions tolerate a diverse set of functional groups, which further strengthens the synthetic impact of this method. The obtained indoles are highly interesting building blocks for the synthesis of 7-substituted indolyl and fused indolyl frameworks. Based on the availability of the starting materials and the enormous gain in molecular complexity, we believe that this method will serve as powerful tool for organic synthesis.

2.4 References

[10] CCDC 1415770 (3q) contain the supplementary crystallographic data. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre.

[12] For details, see Table S1 in the Supporting Information.

2.5 Experimental Section

**General information:** Chemicals were purchased from commercial suppliers and used as delivered. The reagents $1^{[1,2]}$, $4a^{[3,4]}$ have been prepared according to the literature. Dry solvents were dispensed from the solvent purification system MB SPS-800. Deuterated solvents were bought from Euriso-Top. NMR spectra were, if not mentioned otherwise, recorded at room temperature on the following spectrometers: Bruker Avance-III-300, Bruker Avance DRX-300, Bruker-Avance DRX-500 and Bruker Avance-III-500. Chemical shifts are given in ppm and coupling constants in Hz. The following abbreviations were used for $^1$H NMR spectra to indicate the signal multiplicity: s (singlet), brs (broad singlet), d (doublet), t (triplet), q (quartet), quint (quintet), sext (sextet), sept (septet) and m (multiplet) as well as combinations of them. When combinations of multiplicities are given the first character noted refers to the biggest coupling constant. All $^{13}$C NMR spectra were measured with $^1$H-decoupling. The multiplicities mentioned in these spectra [s (singlet, quaternary carbon), d (doublet, CH-group), t (triplet, CH$_2$-group), q (quartet, CH$_3$-group)] were determined by DEPT135 and HSQC spectra. Mass spectra (MS and HRMS) were determined at the chemistry department of the University of Heidelberg under the direction of Dr. J. Gross. EI$^+$-spectra were measured on a JOEL JMS-700 spectrometer. For ESI$^+$-spectra a Bruker ApexQu FT-ICR-MS spectrometer was applied. Infrared Spectroscopy (IR) was processed on an FT-IR Bruker (IF528), IR Perkin Elmer (283) or FT-IR Bruker Vector 22. The solvent or matrix is denoted in brackets. For the most significant bands the wave number $\nu$ (cm$^{-1}$) is given. X-ray crystal structure analyses were measured at the chemistry department of the University of Heidelberg under the direction of Dr. F. Rominger on a Bruker Smart CCD or Bruker APEX-II CCD instrument using Mo-K$_\alpha$-radiation. Diffraction intensities were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using SADABS based on the Laue symmetry of reciprocal space. Heavy atom diffractions were solved by direct methods and refined against F2 with full matrix least square algorithm. Hydrogen atoms were either isotropically refined or calculated. The structures were solved and refined by Dr. F. Rominger using the SHELXTL software package. Gas Chromatography / Mass
Spectrometry (GC/MS) spectra were measured on two different hardware systems: 1. HP 5972 Mass Selective Detector, coupled with a HP 5890 SERIES II plus gas chromatograph. 2. Agilent 5975C Mass Selective Detector, coupled with an Agilent 7890A gas chromatograph. In both cases, as a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and helium was used as the carrier gas. Gas Chromatography (GC) was carried out on a HP 5890 SERIES II plus gas chromatograph. As a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and nitrogen was used as the carrier gas. Melting Points were measured in open glass capillaries in a Büchi melting point apparatus (according to Dr. Tottoli) and were not corrected. Flash Column Chromatography was accomplished using Silica gel 60 (0.04 - 0.063 mm / 230 - 400 mesh ASTM) purchased from Macherey-Nagel or Aluminium oxide (neutral or basic) purchased from Macherey-Nagel. As eluents, mixtures of petroleum ether (PE), ethyl acetate (EA), dichloromethane (DCM) and diethylether (Et₂O) were used. Analytical Thin Layer Chromatography (TLC) was carried out on precoated Macherey-Nagel POLYGRAM® SIL G/UV254 or POLYGRAM® ALOX N/UV254 plastic sheets. Detection was accomplished using UV-light (254 nm), KMnO₄ (in 1.5 M Na₂CO₃ (aq.)), molybdatophosphoric acid (5 % in ethanol), vanillin/H₂SO₄ (in ethanol) or anisaldehyde/HOAc (in ethanol). IUPAC names of the compounds described in the experimental section were determined with the program ACDLabs 12.0.

[a] Reaction conditions: 6a and 2a (0.2 mmol) were heated in PhCF₃ (2ml). [b] isolated yield. [c] Ar = 2, 4-di-tert-butyphenyl.

**Experimental Procedure 1: Synthesis of substituted anthranils**

The syntheses of substituted anthranils was referred to the report of S. Fletcher’s group⁴ with a little modification.

![Reaction Scheme](image)

A round bottom flask equipped with a magnetic stirrer bar was charged with the substituted 2-nitroacylbenezene (3.00 mmol) in EtOAc–MeOH (1:1; 20 mL). SnCl₂ H₂O (9.00 mmol) was added and the reaction was stirred at room temperature.
for 24 h. The reaction was quenched by saturated NaHCO₃ (20 ml), and filtered. The aqueous phase was extracted with EtOAc (3 × 10 mL) and the organic portions combined, washed with H₂O (20 mL), saturated aqueous NaCl (20 mL), dried over Na₂SO₄, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. The characterization of unknown compounds has been listed in part 4.

Experimental Procedure 2: Gold-catalyzed C-H annulation of anthranils with ynamides or aryl alkynyl ethers 4a

A round bottom flask equipped with a magnetic stirrer bar was charged with IPrAuCl (5 mol%, 6.2 mg), AgNTf₂ (5 mol%, 4 mg), and solvent (1 ml). The mixture was stirred for 5 minutes at room temperature. Then the reaction was cooled to -20 °C and the anthranil (0.2 mmol) was added. The alkyne (0.2 mmol) dissolved in solvent (1 ml) was added dropwise over 3 minutes at -20 °C, and reacted at -20 °C for 1 h. The solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. For the non-terminal ynamides, 4 Å MS was added and reacted at 65 °C for 1 h. The characterization of products has been listed in part 4.

Experimental Procedure 4: Gold-catalyzed C-H annulation of alkynes with anthranils

A round bottom flask equipped with a magnetic stirrer bar was charged with IPrAuCl (5 mol%, 6.2 mg), AgNTf₂ (5 mol%, 4 mg), MsOH (10 mol%, 2 mg) and solvent (1 ml). The mixture was stirred 5 minutes at room temperature. Then the anthranil (0.2 mmol) and alkyne (0.2 mmol) dissolved in solvent (1 ml) were added. The reaction was stirred at 65 °C for 4 h. The solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. The characterization of products has been listed in part 4.

Experimental Procedure 5: The hydrolysis of 5a
To the solution of 5a in MeOH (1 ml) was added dropwise 2 N HCl (1 ml). The reaction was stirred at room temperature until the reagent disappeared, monitored by TLC. The reaction was quenched by saturated NaHCO₃. The aqueous phase was extracted with EtOAc (3 × 5 mL) and the organic portions combined, washed with H₂O (10 mL), saturated aqueous NaCl (10 mL), dried over NaSO₄, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. The characterization of product has been listed in part 4.

**Experimental Procedure 6: Seyferth-Gilbert homologation of 3g**

To the mixture of 3g (0.2 mmol), Cs₂CO₃ (0.5 mmol), MeOH (1 ml) and THF (1 ml) was added dropwise the dimethyl (1-diazo-2-oxopropyl)phosphonate (0.4 mmol) at 0 °C. Then, the reaction was stirred 6 h at room temperature. The mixture was washed with H₂O (10 mL), and extracted with EtOAc (3 × 5 mL). The organic portions were combined and washed with saturated aqueous NaCl (10 mL), dried over NaSO₄, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO₂, hexane/EtOAc) to provide the title compound. The characterization of product has been listed in part 4.

**Experimental Procedure 7: Reduction reaction of 3g**

To the solvent of 3g (0.2 mmol) and EtOH (2 ml) was added the NaBH₄ (0.4 mmol), then stirred 2 h at room temperature. The reaction was quenched by H₂O (10 ml), and filtered. The aqueous phase was extracted with EtOAc (3 × 5 mL) and the organic portions combined, washed with H₂O (10 mL), saturated aqueous NaCl (10 mL), dried over NaSO₄, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO₂, hexane/EtOAc) to provide the title compound. The characterization of product has been listed in part 4.

Chapter 3: Gold-Catalyzed Synthesis of Quinolines from Propargyl Silyl Ethers and Anthranils through the Umpolung of a Gold Carbene Carbon

3.1 Introduction

The recent rapid development of gold-catalyzed tandem transformations\textsuperscript{[1]} has afforded atom- and step-economical synthetic approaches to complex heterocyclic scaffolds that are not easily accessible by traditional methods. Following this principle, gold-catalyzed intramolecular nitrene transfers to proximal triple bonds have enabled efficient access to pyrroles,\textsuperscript{[2a,b]} indoles,\textsuperscript{[2c-g]} imidazoles,\textsuperscript{[2h]} pyridines,\textsuperscript{[2i]} isoquinolines,\textsuperscript{[2j,k]} and quinolines.\textsuperscript{[2l,m]} In addition, gold-catalyzed formal [3+2] annulations of nitrenoids with alkynes have attracted attention since these offer more flexible routes to aza-heterocyclic frameworks.\textsuperscript{[3]} For instance, Davies and co-workers disclosed a gold-catalyzed intermolecular reaction of iminopyridinium ylides and ynamides,\textsuperscript{[3a]} delivering polysubstituted oxazoles in high efficiency. The gold-catalyzed syntheses of 2-aminopyrroles using isoxazoles or 2\textit{H}-azirines as nitrene precursors have been achieved by Ye,\textsuperscript{[3c]} Liu\textsuperscript{[3d]} and Huang\textsuperscript{[3e,f]} et al respectively. Recently, we contributed a gold-catalyzed C-H annulation of anthranils with alkynes for the expedient assembly of 7-acylindolyl skeletons\textsuperscript{[3h]} by using the potential of anthranil to act as a binucleophile (Scheme 1, upper part). It is worth noting that all of the above studies rely on \(\alpha\)-imino gold carbenes as key electrophilic intermediates en route to the aza-heterocycles.\textsuperscript{[1k]} If internal alkynes with adjacent methylene moieties are involved in these reactions, the presumed \(\alpha\)-imino gold carbene intermediate is usually quenched by a 1,2-hydride shift/deauration sequence that rapidly delivers \(\alpha, \beta\)-unsaturated imines.\textsuperscript{[3g,h]} As far as we know, although a related migration process has been described by Zhang et al.,\textsuperscript{[4]} gold-catalyzed construction of aza-heterocycles triggered by a 1,2-H shift\textsuperscript{[2a]} onto the \(\alpha\)-imino gold carbene species is no reported.

The quinoline motif is important, it is embedded in numerous natural products,\textsuperscript{[5a-c]} pharmaceutical relevant molecules,\textsuperscript{[5d]} and functional materials.\textsuperscript{[5e,f]} In particular, 2-amino-quinolines exhibit diverse biological activities\textsuperscript{[6]} and have been identified as
a beta-site amyloid precursor protein cleaving enzyme 1 (BACE1) inhibitors for Alzheimer’s disease therapeutics.[7] But compared to the enormous methods for the preparation of quinolines,[8] direct access routes to 2-aminoquinolines from readily available substrates are scarce.[9] The prevalent route still focuses on the C2-amination of quinolines, which usually requires harsh conditions and specific amination reagents.[10] Thus a facile, general, and environmentally benign access to 2-aminoquinolines is still desirable. In continuation of our previous work on gold catalysis,[3h,11] herein we report an unprecedented gold-catalyzed cascade annulation of anthranils[11e] and propargylic silyl ethers, which enables the regiospecific and convergent synthesis of 2-aminoquinolines and quinoline derivatives under mild conditions (Scheme 1, lower part). This reactivity pattern exploits the nucleophilicity of the in situ generated N-aryl-α, β-unsaturated imine (achieved through Umpolung of the electrophilic carbene carbon that reacts in the case of indol formation[3h]). In the presence of a propargylic oxygen atom, a Mukaiyama aldol-type reaction of the enol/enolether with the electrophilic aldehyde moiety derived from the ring opening of the anthranil becomes feasible.

Scheme 1. Upper part: Our previous work on the gold-assisted synthesis of 7-acylindoles through the generation of α-imino gold carbenes from anthranils. Lower part: The new reaction of anthranils with propargylic ethers.
3.2 Results and Discussion

3.2.1 Optimization of the Reaction Conditions

Firstly the effect of the substituent at the propargylic oxygen in ynamides 2 was investigated (Table 1). Only 16% of the product 3aa was obtained from the reaction of 1a with 2a bearing a propargylic alcohol with 5 mol% IPrAuCl/AgNTf₂ in 1,2-DCE at 65 °C for 3 h (entry 1). The yield was significantly increased to 80% by using a ynamide propargylic methyl ether under the same conditions (entry 2). Benzyl and phenyl ethers also afforded moderate yields (entries 3, 4). In order to initiate a Mukaiyama-type aldol reaction,[12] anthranil was reacted with various propargylic silyl ethers (entries 5, 6). The use of tert-butyldimethylsilyl raised the yield to 88% (entry 6). Based on these results, the transformation of anthranil 1a and ynamide propargyl silyl ether 2a (R=TBS) was selected as a model reaction for optimization of the catalysts and solvents (entry 7–13). IPrAuCl/AgNTf₂ turned out to be the best catalyst system. (ArO)₃PAuCl/AgNTf₂ (Ar = 2, 4-di-tert-butylphenyl) also performed outstandingly, with a 87 % yield (entry 7), while only moderate yields were furnished by phosphane ligands. 1,2-DCE gave the best result among the screened solvents. The control experiment without a catalyst showed no conversion (entry 14).

3.2.2 Scope and Limitation

Under the optimized reaction conditions, we started to survey the scope of the reaction with respect to the anthranil. The transformation of differently substituted anthranils with ynamide 2a proceeded smoothly to afford various 3-formyl-2-aminoquinoline derivatives in moderate to excellent yields (Table 2). A broad range of functional groups, including ethers (3ba, 3oa, 3ta), esters (3ca), acetal (3ga), amines (3ka), bromides (3fa, 3ja), fluorides (3da), trifluoromethyl (3la), and unsaturated systems (3ua, 3va), was well compatible under the mild conditions. In general, substituents with electron-donating properties at the anthranil led to higher yields, while anthranils bearing electron-withdrawing groups usually led moderate yields or even disabled the reaction (3sa). This facile access, which allows substituents at each position of the 2-aminoquinoline framework, illustrates the great generality and flexibility of this approach. A fused quinoline (3ha) that can serve as an important substrate in C-H functionalization[13] was smoothly obtained in 72% yield. The connectivity was unambiguously determined by X-ray crystal structure analysis of 3aa.[14] An isoxazole was examined too, but the corresponding 2-aminopyridine was not formed, which might result from decomposition of the unstable N-alkenyl-α, β-unsaturated imine intermediate.[15]

\textsuperscript{[a]} Reaction conditions: 1 (0.24 mmol), 2a (0.2 mmol), and 5 mol\% IPrAuCl/AgNTf\textsubscript{2} at 65 °C for 3 h in 1 mL dry 1,2-DCE. \textsuperscript{[b]} Yield of isolated product.

Next, we applied a series of ynamide propargyl ethers 2 in the reaction with anthranil 1a (Table 3). Mesyl (3ac), nosyl (3af), and oxazolidinone (3ad) substituents at the ynamide nitrogen were all well tolerated. Various substituents on the sulfonamide moiety such as a p-methoxybenzyl group (3ac) and an ester (3ah) turned out to be compatible, delivering good to excellent yields. An N-alkynyl indole provided 2-(indol-1-yl) quinoline (3ae) in 95% yield. Silyl ethers bearing a secondary carbon in the propargylic position gave rise to diversely functionalized ketones (3ai–3an). Ynamide substrates bearing 1°- and 2°-alkyl substitution patterns still afforded moderate yields. Some substituents derived from natural resources, like citronellal (3ak) and lily aldehyde (3am), were successfully introduced by this method. An electron-deficient perfluorinated aryl substituent gave 68% yield (3ao). An X-ray structure analysis of 3aj was conducted to confirm the structural assignment.\textsuperscript{[14]}

![Chemical structures](image-url)
An extension of the synthesis of other C2-substituted quinolines was possible. The less-polarized alkyne 4a (R = n-propyl) and anthranil 1a provided 5a, albeit in only 40% yield. A screening of catalysts and solvents was conducted (Table 4), 70% yield of 5a could be achieved in TFE/1,2-DCE (1:1) using 5 mol% (ArO)₃PAuCl/AgNTf₂ (Ar=2,4-di-tert-butyphenyl). Alkyl, aryl, and alkenyl groups were all compatible under the adjusted conditions (5a-5d). The high regioselectivity can be explained by
the inductive effect of the ethereal oxygen facilitating the reaction of the distal carbon of the triple bond with the oxygen atom.\textsuperscript{[16]} This highly selective synthesis of 2,3-disubstituted quinolines complements the traditional Friedländer synthesis.\textsuperscript{[8a]}

\textsuperscript{[a]} Reaction conditions: 1a (0.4 mmol), 4 (0.2 mmol), 5 mol % (ArO)\textsubscript{3}PAuCl/AgNTf\textsubscript{2} (Ar = 2, 4-di-tert-butylphenyl) in 1 ml TFE/1,2-DCE (1:1) at 65 °C for 12 h. \textsuperscript{[b]} Isolated yield. \textsuperscript{[c]} TFE = CF\textsubscript{3}CH\textsubscript{2}OH; 1,2-DCE = ClCH\textsubscript{2}CH\textsubscript{2}Cl.

3.2.3 Further Applications

A gram-scale synthesis was carried out with a lower catalyst loading (Scheme 2a), to access 3aa in 75% yield. The high potential of the obtained 3-formyl-2-amino-quinolines for further conversions was proved by deprotection of the nosyl group of 3af to the secondary amine 6 (Scheme 2b) and the intramolecular aldol cyclization of 3ah to deliver the pyrrolo[2,3-b]dihydroquinoline framework, which possesses anti-inflammatory, anticonvulsant and antihypertensive properties\textsuperscript{[17]} (Scheme 2c). In addition, the pyrrolo[2,3-b]quinoline derivative 9 could be easily prepared from 3aa in only two steps\textsuperscript{[18]} (Scheme 2d).
3.2.4 Mechanistic investigation

Preliminary mechanistic studies were also conducted. The reaction of anthranil and a propargylic ester afforded the 1,2-acyloxy migration product\textsuperscript{[19]}, which suggests a gold carbene intermediate formed through ring opening of the anthranil, which is
trapped in a subsequent step by the adjacent acetoxy group (Scheme 3a). The cyclization process of the silyl propargyl ether substrate follows a Mukaiyama-type process, which was verified by a $^{18}$O-labelling experiment (Scheme 3b). In contrast, the reaction of a phenyl propargyl ether could be promoted by isotope-labeled water and 81% $^{18}$O was found on product 3aa (Scheme 3c), which indicates that instead the C-O bond is cleaved rather than the O-Si bond in the upper case (Scheme 3d).

### 3.3 Conclusion

In conclusion, the new reaction allows very interesting ring expansions which has a widely range of substates and the excellent tolerance to various functional groups. The mechanistic investigation represents two distinct progresses with respect to the substituent.

### 3.4 References

[14] CCDC 1481674 (3aa), and 1481675 (3aj) contain the supplementary crystallographic data. These data can be obtained free of charge from the cambridge crystallographic data centre.

3.5 Experimental Section

General information: Chemicals were purchased from commercial suppliers and
used as delivered. The reagents 2, 4 have been prepared according to the literature\textsuperscript{1-3}. Deuterated solvents were bought from Euriso-Top. NMR spectra were, if not mentioned otherwise, recorded at room temperature on the following spectrometers: Bruker Avance-III-300, Bruker Avance DRX-300, Bruker-Avance DRX-500 and Bruker Avance-III-500. Chemical shifts are given in ppm and coupling constants in Hz. The following abbreviations were used for $^1$H NMR spectra to indicate the signal multiplicity: s (singlet), brs (broad singlet), d (doublet), t (triplet), q (quartet), quint (quintet), sext (sextet), sept (septet) and m (multiplet) as well as combinations of them. When combinations of multiplicities are given the first character noted refers to the biggest coupling constant. All $^{13}$C NMR spectra were measured with $^1$H-decoupling. The multiplicities mentioned in these spectra [s (singlet, quaternary carbon), d (doublet, CH\textsubscript{2}-group), t (triplet, CH\textsubscript{2}-group), q (quartet, CH\textsubscript{3}-group)] were determined by DEPT135 and HSQC spectra. Mass spectra (MS and HRMS) were determined at the chemistry department of the University of Heidelberg under the direction of Dr. J. Gross. EL$^+$-spectra were measured on a JOEL JMS-700 spectrometer. For ESI$^+$-spectra a Bruker ApexQu FT-ICR-MS spectrometer was applied. Infrared Spectroscopy (IR) was processed on an FT-IR Bruker (IF528), IR Perkin Elmer (283) or FT-IR Bruker Vector 22. The solvent or matrix is denoted in brackets. For the most significant bands the wave number $\nu$ (cm\textsuperscript{-1}) is given. X-ray crystal structure analyses were measured at the chemistry department of the University of Heidelberg under the direction of Dr. F. Rominger on a Bruker Smart CCD or Bruker APEX-II CCD instrument using Mo-K\textsubscript{α}-radiation. Diffraction intensities were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using SADABS based on the Laue symmetry of reciprocal space. Heavy atom diffractions were solved by direct methods and refined against F\textsuperscript{2} with full matrix least square algorithm. Hydrogen atoms were either isotropically refined or calculated. The structures were solved and refined by Dr. F. Rominger using the SHELXTL software package. Gas Chromatography / Mass Spectrometry (GC/MS) spectra were measured on two different hardware systems: 1. HP 5972 Mass Selective Detector, coupled with a HP 5890 SERIES II plus gas chromatograph. 2. Agilent 5975C Mass Selective Detector, coupled with an Agilent 7890A gas chromatograph. In both cases, as a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and helium was used as the carrier gas. Gas Chromatography (GC) was carried out on a HP 5890 SERIES II plus gas
chromatograph. As a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and nitrogen was used as the carrier gas. Melting Points were measured in open glass capillaries in a Büchi melting point apparatus (according to Dr. Tottoli) and were not corrected. Flash Column Chromatography was accomplished using Silica gel 60 (0.04 - 0.063 mm / 230 - 400 mesh ASTM) purchased from Macherey-Nagel or Aluminium oxide (neutral or basic) purchased from Macherey-Nagel. As eluents, mixtures of petroleum ether (PE), ethyl acetate (EA), dichloromethane (DCM) and diethylether (Et₂O) were used. Analytical Thin Layer Chromatography (TLC) was carried out on precoated Macherey-Nagel POLYGRAM® SIL G/UV254 or POLYGRAM® ALOX N/UV254 plastic sheets. Detection was accomplished using UV-light (254 nm), KMnO₄ (in 1.5 M Na₂CO₃ (aq.)), molybdatophosphoric acid (5 % in ethanol), vanillin/H₂SO₄ (in ethanol) or anisaldehyde/HOAc (in ethanol). IUPAC names of the compounds described in the experimental section were determined with the program ACDLabs 12.0⁹.

**Experimental Procedure 1: Synthesis of substituted anthranils**

![Chemical Structure](image)

**Condition A⁹**: A round bottom flask equipped with a magnetic stirrer bar was charged with the substituted 2-nitroacylbenzene (3.00 mmol) in EtOAc–MeOH (1:1; 20 mL). SnCl₂·H₂O (9.00 mmol) was added and the reaction was stirred at room temperature for 24 h. The reaction was quenched by saturated NaHCO₃ (20 ml), and filtered. The aqueous phase was extracted with EtOAc (3 × 10 mL) and the organic portions were combined, washed with H₂O (20 mL), saturated aqueous NaCl (20 mL), dried over Na₂SO₄, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. The characterization data of unknown compounds has been listed in part 3.

**Condition B⁶**: A round bottom flask equipped with a magnetic stirrer bar was charged with the substituted 2-nitroacylbenzene (1.00 mmol) in conc. HCl ( 3 ml). SnCl₂·H₂O (4 mmol) was added and the reaction was stirred at 10 °C for 30 mins. The reaction was quenched with saturated NaHCO₃ (20 ml), and filtered. The aqueous phase was extracted with EtOAc (3 × 10 mL) and the organic portions were combined,
washed with H₂O (20 mL), saturated aqueous NaCl (20 mL), dried over NaSO₄, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. The characterization data of unknown compounds has been listed in part 3.

**Experimental Procedure 2: Gold-catalyzed transformation of anthranils with ynamide propargylic ethers**

A round bottom flask equipped with a magnetic stirrer bar was charged with IPrAuCl (5 mol%, 6.2 mg), AgNTf₂ (5 mol%, 4 mg), and solvent (1 ml). The mixture was stirred for 5 minutes at room temperature. Then the ynamide propargylic ethers (0.2 mmol) and anthranil (0.24 mmol) were added. The reaction was heated at 65 °C for 3 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. The characterization data of the products are listed in part 3.

**Gram-scale reaction:** A round bottom flask equipped with a magnetic stirrer bar was charged with IPrAuCl (1 mol%, 31 mg), AgNTf₂ (1 mol%, 20 mg), and solvent (20 ml). The mixture was stirred for 10 minutes at room temperature. Then the ynamide propargylic ethers (5 mmol, 1.76 g) and anthranil (6 mmol, 0.71 g) were added. The reaction was heated at 65 °C for 3 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc = 8:1) to provide the product in 75 % yield (1.28 g).

**Experimental Procedure 3: Gold-catalyzed transformation of non-polarized propargylic ethers with anthranils**

A round bottom flask equipped with a magnetic stirrer bar was charged with (ArO)₃PAuCl (5 mol%, 8.8 mg) (Ar = 2, 4- di-tert-butylphenyl), AgNTf₂ (5 mol%, 4 mg) in 1 ml TFE/1,2-DCE co-solvent (ratio 1:1). The mixture was stirred for 5 minutes at room temperature. Then the anthranil (0.4 mmol) and the alkyne (0.2 mmol) were added. The reaction was stirred at 65 °C for 12 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by
column chromatography (SiO$_2$, hexanes/EtOAc) to provide the title compound. The characterization data of the products has been listed in part 3.

**Experimental Procedure 4: Removal of the nosyl group of 3af**

To the solution of 3af (0.2 mmol) and K$_2$CO$_3$ (0.6 mmol) in MeCN (1 ml) PhSH (0.4 mmol) was added. The reaction was stirred at room temperature until complete consumption of the starting material, monitored by TLC (about 1 h). The reaction was washed with H$_2$O (15 mL), extracted with EtOAc (3 × 5 mL) and the organic portions were combined, dried over NaSO$_4$, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO$_2$, hexanes/EtOAc) to provide the title compound 6. The characterization data of the obtained product is listed in part 3.

**Experiment Procedure 5: The synthesis of 7 from 3ah**

The mixture of 3ah (0.2 mmol), MeCN (1 ml) and Et$_3$N (0.4 mmol) was stirred 48 h at room temperature. The mixture was washed with H$_2$O (10 mL), and extracted with EtOAc (3 × 5 mL). The organic portions were combined and washed with saturated aqueous NaCl (10 mL), dried over NaSO$_4$, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO$_2$, hexane/EtOAc) to provide the title compound 7. The characterization data of the product is listed in part 3.

**Experimental Procedure 6: The synthesis of 9 from 3aa**

To a mixture of 3aa (0.5 mmol), K$_2$CO$_3$ (1 mmol) in MeOH (2 ml) was added the Bestman-Ohira reagent and the reaction was stirred for 12 h at room temperature to afford the product 8. Then, the compound 8 was heated at 80 °C for 24 h catalyzed by 10 mol% AuBr$_3$ in 1 ml DCE under argon protection. The mixture was washed with H$_2$O (10 mL), and extracted with EtOAc (3 × 5 mL). The organic portions were combined and washed with saturated aqueous NaCl (10 mL), dried over NaSO$_4$, filtered and reduced in vacuo. The residue was purified by column chromatography (SiO$_2$, hexane/EtOAc) to provide the product 9. The characterization of product has been listed in part 3.
Mechanistic Investigation

Conditions according to procedure 3. The result was monitored by GC/MS without isolation.
The operation was the same as procedure 2, in addition 5 equiv. $\text{H}_2^{18}\text{O}$ were added to the reaction mixture before heating. The result was detected by NMR and GC/MS without isolation.
Characterization

Compound 1d: Yield 80 %, colourless soild, mp: 46-47 °C; $^1$H NMR (300 MHz, CDCl$_3$) $\delta = 9.09$ (s, 1 H), 7.67-7.60 (m, 1 H), 7.18-7.08 (m, 2 H) ppm; $^{13}$C NMR (75 MHz, CDCl$_3$) $\delta = 158.9$ (J = 245.4 Hz, s), 154.5 (J = 10.8 Hz, d), 154.3 (s), 124.2 (J = 31.2 Hz, d), 117.8 (J = 9.3 Hz, d), 117.4 (J = 11.5 Hz, s), 100.8 (J = 24.9Hz, d) ppm; IR (ATR): $\tilde{\nu} = 3127, 1651, 1575, 1552, 1524, 1469, 1410, 1358, 1326, 1270, 1227, 1155, 1131, 955, 922, 885, 851, 812, 742$ cm$^{-1}$; HRMS (EI) m/z calcd for C$_7$H$_4$FNO: 137.0277; found: 137.0276.

Compound 1k: Yield 43 %, yellow green soild, mp: 50-51 °C; $^1$H NMR (500 MHz, CDCl$_3$) $\delta = 8.83$ (s, 1 H), 7.41-7.38 (m, 1 H), 6.88-6.84 (m, 1 H), 6.36 (s, 1 H), 3.04 (s, 6 H) ppm; $^{13}$C NMR (125 MHz, CDCl$_3$) $\delta = 157.9$ (s), 153.0 (d), 151.4 (s), 119.8 (d), 118.7 (d), 114.1 (s), 87.4 (d), 40.6 (q, 2 C) ppm; IR (ATR): $\tilde{\nu} = 3446, 3092, 2919, 2854, 2821, 2489, 2359, 2215, 2071, 1910, 1868, 1646, 1574, 1509, 1483, 1443, 1396, 1356, 1303, 1261, 1225, 1151, 1114, 1063, 958, 917, 849, 793, 735, 715, 639$ cm$^{-1}$; HRMS (EI) m/z calcd for C$_9$H$_{10}$N$_2$O: 162.0793; found: 162.0785.

Compound 1l: Yield 78 %, light yellow oil; $^1$H NMR (500 MHz, CDCl$_3$) $\delta = 9.26$ (s, 1 H), 8.01 (s, 1 H), 7.74 (d, J = 9.0 Hz, 1 H), 7.17 (d, J = 9.0 Hz, 1 H) ppm; $^{13}$C NMR (125 MHz, CDCl$_3$) $\delta = 155.6$ (d), 154.8 (s), 133.0 (J = 32.1 Hz, s), 123.3 (J = 271 Hz, s), 121.7 (d), 120.3 (J = 2.5 Hz, d), 118.5 (s), 114.2 (J = 5 Hz, d) ppm; IR (ATR): $\tilde{\nu} = 3142, 3122, 2928, 2362, 1914, 1754, 1651, 1627, 1568, 1521, 1464, 1417, 1389, 1347, 1285, 1255, 1240, 1191, 1155, 1105, 936, 925, 884, 827, 787, 746, 661$ cm$^{-1}$; HRMS (EI) m/z calcd for C$_8$H$_4$F$_3$NO: 187.0245; found: 187.0218.
Compound 1n: Yield 90 %, light yellow soild, mp: 46–47 °C; ¹H NMR (500 MHz, CDCl₃) δ = 9.22 (s, 1 H), 7.51 (d, J = 9.0 Hz, 1 H), 7.34 (d, J = 7.0 Hz, 1 H), 6.97 (dd, J = 7.0 Hz and 9.0 Hz, 1 H) ppm; ¹³C NMR (125 MHz, CDCl₃) δ = 156.0 (d), 154.7 (s), 130.0 (d), 124.8 (d), 121.3 (s), 119.4 (s), 118.5 (d) ppm; IR (ATR): ṽ = 3120, 2925, 2854, 2819, 1750, 1635, 1610, 1581, 1552, 1512, 1463, 1385, 1318, 1248, 1212, 1155, 1120, 1024, 978, 922, 879, 830, 775, 741, 678, 622 cm⁻¹; HRMS (EI) m/z calcd for C₇H₄ClNO: 152.9981; found: 152.9987.

Compound 1t: Yield 60 %, light yellow soild, mp: 131–132 °C; ¹H NMR (500 MHz, CDCl₃) δ = 6.68 (s, 1 H), 6.48 (s, 1 H), 3.94 (s, 3 H), 3.90 (s, 3 H), 2.68 (s, 3 H) ppm; ¹³C NMR (125 MHz, CDCl₃) δ = 162.5 (s), 155.24 (s), 155.2 (s), 148.8 (s), 111.0 (s), 94.4 (d), 91.1 (d), 56.2 (q), 55.9 (q), 11.7 (q) ppm; IR (ATR): ṽ = 3082, 3009, 2970, 2841, 1737, 1656, 1583, 1533, 1502, 1465, 1451, 1434, 1376, 1317, 1243, 1224, 1204, 1173, 1072, 1030, 1008, 978, 841, 820, 737, 724 cm⁻¹; HRMS (EI) m/z calcd for C₁₀H₁₁NO₃: 193.0739; found: 193.0735.

Compound 3aa: Yield 88 %, colourless soild, mp: 152–154 °C; ¹H NMR (300 MHz, CDCl₃) δ = 10.58 (s, 1 H), 8.84 (s, 1 H), 8.03–8.00 (m, 1 H), 7.86–7.74 (m, 2 H), 7.67–7.57 (m, 1 H), 7.36 (d, J = 8.1 Hz, 2 H), 7.21 (d, J = 7.8 Hz, 2 H), 3.32 (s, 3 H), 2.41 (s, 3 H) ppm; ¹³C NMR (125 MHz, CDCl₃) δ = 188.9 (d), 153.0 (s), 148.5 (s), 144.4 (s), 138.6 (d), 132.32 (s), 132.31 (d), 129.5 (d, 2 C), 129.4 (d), 128.7 (d), 128.6 (d, 2 C), 127.8 (d), 127.7 (s), 126.6 (s), 36.7 (q), 21.7 (q) ppm; IR (ATR): ṽ = 2968, 2926, 2883, 1717, 1688, 1615, 1584, 1494, 1459, 1409, 1386, 1372, 1345, 1304, 1294, 1266, 1185, 1159, 1115, 1087, 1049, 1016, 1005, 970, 940, 920, 890, 869, 817, 806, 792, 779, 759, 751, 706, 670, 622 cm⁻¹; HRMS (EI) m/z calcd for C₁₈H₁₆N₂O₅S:
Compound 3ba: Yield 93 %, colourless soild, mp: 170-171 °C; ¹H NMR (300 MHz, CDCl₃) δ = 10.57 (s, 1 H), 8.71 (s, 1 H), 7.73-7.66 (m, 1 H), 7.46-7.31 (m, 3 H), 7.25-7.16 (m, 3 H), 3.95 (s, 3 H), 3.29 (s, 3 H), 2.41 (s, 3 H) ppm; ¹³C NMR (75 MHz, CDCl₃) δ = 189.2 (d), 158.7 (s), 151.0 (s), 144.7 (s), 144.2 (s), 137.0 (d), 132.4 (s), 130.0 (d), 129.4 (d, 2 C), 128.6 (d, 2 C), 127.9 (s), 127.7 (s), 125.5 (d), 106.2 (d), 55.8 (q), 36.7 (q), 21.6 (q) ppm; IR (ATR): Ṽ = 3086, 3056, 2998, 2966, 2948, 2935, 2875, 1698, 1620, 1589, 1500, 1451, 1423, 1394, 1375, 1352, 1324, 1307, 1263, 1226, 1186, 1158, 1138, 1117, 1087, 1036, 1025, 958, 943, 904, 864, 834, 819, 801, 783, 772, 730, 666, 625, 611 cm⁻¹; HRMS (EI) m/z calcd for C₁₉H₁₈N₂O₄S: 370.0987; found: 370.0971.

Chapter 4: Counteranion-Directed Divergent [4+2]
Annulation of Benzofurazans with Ynamides by Gold and Platinum Catalysis: Switchable Access to Quinoxaline N-Oxides/ Quinoxalines

4.1 Introduction

Quinoxaline N-oxides and quinoxalines are of great significance owning to their important biological properties, including antiinflammatory, antimicrobial and antitumoral activities. This created increasing attentions from the synthetic community.[1] The condensation of o-phenylenediamine with aldehydes/ketones is the prevalent entry to quinoxalines, despite regioselectivity frustration.[2] Various oxidation approaches toward quinoxaline N-oxides from the corresponding quinoxalines also exist.[3] However, the specific synthesis of quinoxaline mono-N-oxide is still a challenge due to easy over-oxidations, low regioselectivity between both nitrogen atoms and limited tolerance of functional groups. Moreover, these linear synthetic strategies are usually accompanied with low atom-economy and low yields. Thus, the exploration of versatile protocols for the convergent assembly of functionalized quinoxaline mono-N-oxides[4a] and quinoxalines[4b-e] remains highly desirable.

Catalytic alkyne activation by π acids, especially gold and platinum, had immense impact on synthetic chemistry, greatly promoting the facile and flexible construction of intricate heterocyclic scaffolds.[5] In recent years, α-imino gold carbene-mediated intramolecular transfer of nitrene to alkynes enabled novel and atom-economical accesses to diverse aza-heterocycles.[6-11] For instance, our group contributed gold-catalyzed formal [3+2] and [4+2] cycloadditions of alkynes with anthranils toward the 7-acylindole and 2-aminoquinoline skeleton respectively.[10] A concise route to 2-aminopyroles through gold-catalyzed [3+2] annulation of ynamides with isoxazoles as nitrene equivalent was reported by Ye and co-workers.[11a] Divergent to gold catalysis, α-imino platinum carbenoids turned out to be more oxophilic giving rise to a [5+2] annulation strategy (Scheme 1, a).[12]
In most gold and platinum-catalyzed transformations, the counteranion is generally considered as an accelerating factor and the counteranion effect on the reaction selectivity or the catalyst structure is less focused. Herein we presented Au/Pt-catalyzed counteranion-directed selective syntheses of quinoxaline \( N \)-oxides and quinoxalines. Benzofurazan was selected as a new nucleophilic “nitrenoid” as potential \( \alpha \)-imino metal carbenoid precursor. Despite its commercial availability and wide existence in medical molecules, the chemistry of this compound is rare. In contrast to isoxazole as reactant, both gold and platinum carbenes, generated from the reaction of ynamide with benzofurazan, triggered the same \([4+2]\) annulation without a chemoselective divergence. Nevertheless, the choice of the counteranion had the crucial influence on switching access to different products. While the deoxidized product quinoxaline resulted from the bulky \( \text{NTf}_2^-\) anion, chloride as counterion led to quinoxaline mono-\( N \)-oxide as the major product (Scheme 1, b). Further, counteranion-induced alternative cyclization processes were indicated by mechanistic investigations.

**Scheme 1.** Switchable access to aza-heterocyclic compounds.
4.2 Results and Discussion

4.2.1 Optimization of the Reaction Conditions

We initially surveyed the reaction of 2 equiv. benzofurazan 1a and ynamide 2a (R = Me) with 10 mol % PtCl₂ in PhMe at 80 °C for 24 h (Table 1, entry 1). The products 3a and 4a were obtained in 30 % and 13 % respectively. Both solid state molecular structures were determined by single-crystal X-ray diffraction.\[15a\] In order to increase the selectivity, various ligands and anions were examined (entry 2-9). PtCl₂ in combination with highly hindered phosphite ligand L₄ gave the best result with 80 % yield of 3a and 12 % yield of 4a (entry 8), whereas PtI₂ delivered low yield and selectivity (entry 9). To our delight, the transformation of benzofurazan 1a with ynamide 2b (R = Bn) specifically produced 3a in 83 % yield with L₄ as ligand (entry 10). Taking advantage of AuCl/L₄ or AuCl₃ also afforded the excellent selectivity, albeit in lower yield (entry 11, 13). The yield of 3a could be raised to 79 % by AuCl without any ligand (entry 12). In contrast, 10 mol% AgNTf₂ as additive reversed the product selectivity, favoring the quinoxaline product. Under these conditions 1,2-DCE performed better in yield than toluene (entry 14). Based on this result, we chose the reaction of 4 equiv. benzofurazan 1a and ynamide 2a in 1,2-DCE as model system to optimize the catalyst (entry 15-22). Among gold and platinum catalysts, L₁AuCl/AgNTf₂ showed higher catalytic activity and selectivity, delivering 4a in 67 % yield (entry 18). Besides of NTf₂⁻, the other bulky anion SbF₆⁻ also offered good selectivity of 4a although with moderate yield (entry 19). The control experiment demonstrated the catalytic capacity of gold and platinum (entry 23). Moreover, the absence of silver salt has a slightly negative impact on the selectivity (entry 24). Finally, PtCl₂/L₄ qualified for the syntheses of quinoxaline N-oxides, while quinoxalines were favorably prepared with the L₁AuCl/AgNTf₂ catalyst system.

### 4.2.2 Scope and Limitation

Under the optimized reaction conditions, we began to evaluate the scope of ynamides (Table 2). First the treatment of diverse ynamides with benzofurazan 1a was conducted under condition A. A broad set of protecting groups and substituents at the R\textsuperscript{2}-position were checked (3a-f). Ms, Bs and the easily removable nosyl group were well tolerated. Benzyl substituted ynamides provided higher yield than methyl. Then, our attention was turned to variations on the aryl moiety of the ynamide. A wide range of functional groups, including trifluoromethyl (3i), fluoride (3h, 3s), bromide (3l, 3n), ester (3m) and methoxyl moieties (3o, 3q), were all compatible, delivering the corresponding functionalized quinoxaline N-oxides in good to excellent yields. Naphthyl, heterocyclic and even alkenyl substituted ynamides also proceeded smoothly (3r-3t-v). Subsequently, the generality of ynamides was also examined under condition B (4a-m). A range of substituted quinoxalines was also successfully prepared in moderate to good yields with fine tolerance of functional groups.

[a] Condition A: 1a (0.2 mmol), 2 (0.1 mmol), and 10 mol% PtCl₂/L₄ at 80 °C for 24 h in toluene. Condition B: 1a (0.4 mmol), 2 (0.1 mmol), and 10 mol% L₁AuCl/AgNTf₂ at 80 °C for 24 h in 1,2-DCE. [b] Isolated yields.
In addition to benzofurazan, a variety of substituted derivatives were also explored to suit the reaction with ynamides under condition A and B (Table 3). Gratifyingly, methoxy (3x, 3ab-c, 4p-q), bromide (3y, 4o) and amide (3aa) were all tolerated delivering versatile scaffolds for further decoration. For common approaches to quinoxalines, the control of regioselectivity remains a challenge\(^{[2, 4d-e]}\). Hence, a few attempts were made on the regiospecific synthesis of quinoxalines N-oxides and quinoxalines following this method. In the case of 3ab and 4p, the conjugative effect of the β-methoxy group enhances the nucleophilicity of the adjacent nitrogen which induces good regioselectivity. An analogous substituent effect attributes to the formation of product 3aa. An excellent regioselectivity was obtained by the reaction of α-substituted benzofurazans, in which one of the nitrogen was shielded by an additional substituent (3ac-d, 4q-r). To underline the correct structural assignments the major isomers of 3ab, 4p and 4r were determined by single-crystal X-ray analysis.\(^{[15b]}\)

4.2.3 Further Applications

Quinoxaline N-oxides are considered as significant intermediates in organic synthesis. By taking the advantage of N-oxides as directing group, the further decoration could be facilely accomplished by direct C-H functionalization (Scheme 2).\(^{[16]}\) As example, the quinoxaline N-oxide 3b was suitable for iridium-catalyzed selective C8-amination (3b-1). The iodinated product 3b-2 was also prepared from 3a with N-iodosuccinimide via a similar strategy.

![Scheme 2. C-H functionalization of quinoxaline N-oxide.](image)

4.2.3 Mechanistic Investigation

Preliminary mechanistic investigations on the counteranion-mediated selectivity
switch were investigated next. The treatment of quinoxaline $N$-oxide and ynamide with $\text{L1AuCl/AgNTf}_2$ offered the quinoxaline accompanied by oxidized by-products (Scheme 3, a). However, under the same condition only few oxidized by-products were observed for the transformation of benzofurazan with the same ynamide (Scheme 3, b). This result suggests that the quinoxaline is not formed by the deoxidization of its corresponding quinoxaline $N$-oxide. On the basis of above studies, a probable reaction mechanism is shown in Scheme 4. The benzofurazan initially reacts with the metal-activated ynamide to generate a $\alpha$-imino metal carbene $A/A'$ with the in-situ formation of a nitrosyl group. Then, the resulting carbene intermediate can follow different pathways. In the case of a chloride ion, the metal carbene $A$ is attacked by the nitrosyl group furnishing metal-ligated cyclized intermediate $B$, which subsequently produces quinoxaline $N$-oxide after metal elimination (path a). On the other hand, when the bulky ion $\text{NTf}_2^-$ is involved, due to the higher electrophilicity of exposed metal core a $[2+2]$ cycloaddition of nitrosyl group and metal carbene $A'$ is preferred.\(^{[17]}\) The quinoxaline is generated by a metathesis process losing the metallic oxide, which might decompose to regenerate the active metal catalyst (path b).

**Scheme 4.** Plausible mechanism.

### 4.3 Summary

In summary, we described gold and platinum-catalyzed counteranion-controlled divergent $[4+2]$ cycloaddition of benzofurazans and ynamides. The tunable protocol provided convenient and regioselective syntheses of quinoxaline mono-$N$-oxides and quinoxalines from common starting materials. A wide range of functional groups were
well tolerated. Mechanistic studies disclosed the counteranion effect on the selectivity of the products via alternative cyclization pathways.

4.5 Experimental Section

**General information:** Chemicals were purchased from commercial suppliers and used as delivered. The benzo[110]furan is bought from SigmaAldrich. Substrates 1 and 2 were prepared according to related literatures.[1-5] Deuterated solvents were bought from Euriso-Top. NMR spectra were, if not mentioned otherwise, recorded at room temperature on the following spectrometers: Bruker Avance-III-300, Bruker Avance DRX-300, Bruker-Avance DRX-500 and Bruker Avance-III-500. Chemical shifts are given in ppm and coupling constants in Hz. The following abbreviations were used for $^1$H NMR spectra to indicate the signal multiplicity: s (singlet), brs (broad singlet), d (doublet), t (triplet), q (quartet), quint (quintet), sext (sextet), sept (septet) and m (multiplet) as well as combinations of them. When combinations of multiplicities are given the first character noted refers to the biggest coupling constant. All $^{13}$C NMR spectra were measured with $^1$H-decoupling. The multiplicities mentioned in these spectra [s (singlet, quaternary carbon), d (doublet, CH-group), t (triplet, CH$_2$-group), q (quartet, CH$_3$-group)] were determined by DEPT135 and HSQC spectra. Mass spectra (MS and HRMS) were determined at the chemistry department of the University of Heidelberg under the direction of Dr. J. Gross. EI$^+$-spectra were measured on a JOEL JMS-700 spectrometer. For ESI$^+$-spectra a Bruker ApexQu FT-ICR-MS spectrometer was applied. Infrared Spectroscopy (IR) was processed on an FT-IR Bruker (IF528), IR Perkin Elmer (283) or FT-IR Bruker Vector 22. The solvent or matrix is denoted in brackets. For the most significant bands the wave number $\nu$ (cm$^{-1}$) is given. X-ray crystal structure analyses were measured at the chemistry department of the University of Heidelberg under the direction of Dr. F. Rominger on a Bruker Smart CCD or Bruker APEX-II CCD instrument using Mo-K$_\alpha$-radiation. Diffraction intensities were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using SADABS based on the Laue symmetry of reciprocal space. Heavy atom diffractions were solved by direct methods and refined against F2 with full matrix least square algorithm. Hydrogen atoms were either isotropically refined or calculated. The structures were solved and refined by Dr. F. Rominger using the SHELXTL software package. Gas Chromatography / Mass Spectrometry (GC/MS) spectra were measured on two different hardware systems: 1. HP 5972 Mass Selective Detector, coupled with a HP 5890 SERIES II plus gas
chromatograph. 2. Agilent 5975C Mass Selective Detector, coupled with an Agilent 7890A gas chromatograph. In both cases, as a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and helium was used as the carrier gas. Gas Chromatography (GC) was carried out on a HP 5890 SERIES II plus gas chromatograph. As a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and nitrogen was used as the carrier gas. Melting Points were measured in open glass capillaries in a Büchi melting point apparatus (according to Dr. Tottoli) and were not corrected. Flash Column Chromatography was accomplished using Silica gel 60 (0.04 - 0.063 mm / 230 - 400 mesh ASTM) purchased from Macherey-Nagel or Aluminium oxide (neutral or basic) purchased from Macherey-Nagel. As eluents, mixtures of petroleum ether (PE), ethyl acetate (EA), dichloromethane (DCM) and diethylether (Et₂O) were used. Analytical Thin Layer Chromatography (TLC) was carried out on precoated Macherey-Nagel POLYGRAM® SIL G/UV254 or POLYGRAM® ALOX N/UV254 plastic sheets. Detection was accomplished using UV-light (254 nm), KMnO₄ (in 1.5 M Na₂CO₃ (aq.),) molybdatophosphoric acid (5 % in ethanol), vanillin/H₂SO₄ (in ethanol) or anisaldehyde/HOAc (in ethanol). IUPAC names of the compounds described in the experimental section were determined with the program ACDLabs 12.0°.

Experimental Procedures

A round bottom flask equipped with a magnetic stirrer bar was added 10 mol% PtCl₂ (2.6 mg), 10 mol% L₄ (9.2 mg), 1 (0.2 mmol), 2 (0.1 mmol) and toluene (1 ml). The reaction was heated at 70 °C for 24 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound. The characterization data of the products are listed in part 3.
A round bottom flask equipped with a magnetic stirrer bar was charged with L1AuCl (10 mol%, 6.5 mg), AgNTf₂ (10 mol%, 4 mg), and 1,2-DCE (1 ml). The mixture was stirred for 5 minutes at room temperature. Then the benzofurazan 1 (0.4 mmol) were added. The ynamides 2 (0.1 mmol) dissolved in 1 ml 1,2-DCE was dropwisely added into above mixture over 10 h at 70 °C by syringe pump. The reaction continued to heat for 12 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound.

A round bottom flask equipped with a magnetic stirrer bar was charged with [Cp*IrCl₂]₂ (2 mol%, 3.2 mg), AgNTf₂ (8 mol%, 3.2 mg), quinoxaline N-oxide (0.1 mmol), TsN₃ (0.15 mmol) and 1,2-dichloroethane (0.5 ml). The mixture heated at 50 °C for 12 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound.

A round bottom flask equipped with a magnetic stirrer bar was charged with [Cp*RhCl₂]₂ (4 mol%, 2.5 mg), AgNTf₂ (16 mol%, 6.4 mg), quinoxaline N-oxide (0.1 mmol), NIS (0.15 mmol) and 1,2-dichloroethane (0.5 ml) under nitrogen atmosphere. The mixture was heated at 50 °C for 12 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound.
A round bottom flask equipped with a magnetic stirrer bar was charged with L1AuCl (10 mol%, 6.5 mg), AgNTf₂ (10 mol%, 4 mg), and 1,2-DCE (1 ml). The mixture was stirred for 5 minutes at room temperature. Then the ynamide (0.1 mmol) and quinoxaline N-oxide (0.1 mmol) were added. The mixture was heated for 1 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the title compound.

**Characterization**

**Compound 3a:** Yield 80%, Rₚ = 0.25 (PE/EA = 4:1), colourless soild, mp: 195-196 °C; ¹H NMR (500 MHz, CDCl₃) δ = 8.64-8.58 (m, 1 H), 8.01-7.95 (m, 1 H), 7.87-7.82 (m, 1 H), 7.82-7.76 (m, 1 H), 7.74-7.67 (m, 4 H), 7.63-7.53 (m, 3 H), 7.35-7.30 (m, 2 H), 2.94 (s, 3 H), 2.49 (s, 3 H) ppm; ¹³C NMR (125 MHz, CDCl₃) δ = 151.1 (s), 144.1 (s), 142.0 (s), 140.8 (s), 136.8 (s), 135.1 (s), 131.8 (d), 130.6 (d), 130.4 (d), 129.8 (d), 129.5 (d), 129.4 (d), 129.0 (d), 128.9 (d), 128.6 (d), 119.5 (d), 36.9 (q), 21.7 (q) ppm; IR (ATR): ʋ = 3064, 2957, 1717, 1597, 1575, 1537, 1497, 1481, 1453, 1397, 1344, 1297, 1237, 1162, 1117, 1084, 1032, 1018, 995, 902, 867, 814, 767, 728, 699, 666, 618 cm⁻¹; HRMS (ESI) m/z calcd for [M+H]⁺: 406.1220; found: 406.1223.
**Compound 3b:** Yield 83%, $R_f = 0.24$ (PE/EA = 4:1), colourless soild, mp: 194-195 °C; $^1$H NMR (500 MHz, CDCl$_3$) $\delta$ = 8.47-8.42 (m, 1 H), 7.98-7.94 (m, 1 H), 7.79-7.72 (m, 1 H), 7.70-7.64 (m, 1 H), 7.45-7.35 (m, 3 H), 7.35-7.29 (m, 2 H), 7.22-7.15 (m, 2 H), 7.14-7.07 (m, 1 H), 7.05-6.93 (m, 4 H), 6.78-6.67 (m, 2 H), 4.48 (s, 2 H), 2.39 (s, 3 H) ppm; $^{13}$C NMR (125 MHz, CDCl$_3$) $\delta$ = 149.6 (s), 144.3 (s), 142.7 (s), 141.9 (s), 136.8 (s), 135.3 (s), 134.0 (s), 131.8 (d), 130.7 (d), 130.6 (d), 129.8 (d), 129.5 (d), 129.4 (d), 129.0 (d), 128.9 (s), 128.5 (d), 128.2 (d), 128.1 (d), 119.6 (d), 53.7 (t), 21.7 (q) ppm; IR (ATR): $\tilde{\nu}$ = 3067, 2931, 1911, 1599, 1578, 1530, 1495, 1479, 1454, 1402, 1375, 1344, 1300, 1225, 1184, 1152, 1117, 1088, 1049, 1019, 993, 963, 915, 892, 866, 810, 769, 722, 700, 677, 663, 653, 630, 617 cm$^{-1}$; HRMS (ESI) m/z calcd for [M+H]$^+$: 482.1533; found: 482.1532

**Compound 3c:** Yield 70%, $R_f = 0.1$ (PE/EA = 4:1), colourless soild, mp: 198-199 °C; $^1$H NMR (500 MHz, CDCl$_3$) $\delta$ = 8.53-8.47 (m, 1 H), 7.99-7.94 (m, 1 H), 7.79-7.73 (m, 1 H), 7.72-7.66 (m, 1 H), 7.63-7.57 (m, 2 H), 7.52-7.40 (m, 3 H), 3.12 (s, 3 H), 2.90 (s, 3 H) ppm; $^{13}$C NMR (125 MHz, CDCl$_3$) $\delta$ = 151.3 (s), 141.9 (s), 139.8 (s), 136.9 (s), 131.9 (d), 130.6 (d), 130.2 (d), 130.0 (d), 129.5 (d), 128.7 (d), 128.5 (s), 119.6 (d), 39.5 (q), 37.0 (q) ppm; IR (ATR): $\tilde{\nu}$ = 2959, 2903, 2867, 1716, 1600, 1578, 1509, 1484, 1454, 1394, 1362, 1346, 1300, 1240, 1202, 1187, 1161, 1131, 1108, 1084, 1017, 1004, 896, 875, 831, 810, 788, 773, 758, 731, 717, 704, 675, 660, 635, 624, 615 cm$^{-1}$; HRMS (ESI) m/z calcd for [M+H]$^+$: 330.0907; found: 330.0907.

Chapter 5: Gold-Catalyzed Oxidative [2+2+1] Annulation of Ynamides with Quinoxaline N-Oxides toward Fully-Functionalized Furans

5.1 Introduction

Gold-catalyzed oxidative cyclizations have attracted enormous attention as powerful, flexible and abundant tool for the construction of heterocyclic frameworks.\[1\] Therein the facile alkyne oxidation by N-oxides to access α-oxo gold carbenes instead of using hazardous diazo carbonyl compounds as carbenoid precursors significantly expands the substrate generality and the synthetic horizon of gold catalysis.\[2,3\] However, the published cyclization processes involve mostly intramolecular trappings of α-oxo gold carbenes via tethered nucleophiles.\[4\] Currently, intermolecular cyclization patterns for α-oxo gold carbenes is still limited to the reaction with external nitriles\[5a\] or amides\[5b\] leading to oxazole derivatives (Scheme 1 A). For more challenging C-nucleophiles, despite of spectacular achievements on intermolecular oxygenative C-C bond couplings of alkynes with electron-rich arenes via N-oxides,\[6\] further tandem cyclizations are no reported. Moreover, the exploitation of new C-nucleophiles in combination with matching N-oxides for gold-catalyzed oxygenative reactions with alkynes remains highly desirable.

Ynamides are easily accessible and significant building blocks for synthetic chemists.\[7\] Due to the polarization of the triple bond, ynamides possess both electrophilic and nucleophilic properties. In recent years, the introduction of ynamides into gold catalysis has greatly promoted the boom of ynamide chemistry.\[8\] Yet, most of transformations were invoked by only one role of the ynamide, either acting as an electrophile or a nucleophile. A scarce case of a gold-catalyzed ynamide self-dimerization enabled by its amphoteric character was reported by Skrydstrup and co-workers (Scheme 1 B).\[9\] Inspired by this study and in continuation of our interest on ynamide transformations,\[10\] we envisaged that a-oxo gold carbene generated via the electrophilic character of the ynamide would be electrophilic enough to be trapped via the nucleophilic character of the other molecule of ynamide. In fact, the major
obstacle for the reaction design was that under the oxidative condition the \textit{in-situ} generated gold carbenes are easily over-oxidized by nucleophilic $N$-oxides, as competing reaction to the presumed trapping with the weakly nucleophilic ynamide.

Herein, we achieved the unique gold-catalyzed oxidative [2+2+1] annulation of two molecules of ynamide with an oxygen atom transferred from 2,3-dichloroquinoxaline $N$-oxide (Scheme 1 C). This give rise to densely substituted furans that are widely embed in functional materials and pharmaceuticals.\[^{11}\] 2,3-Dichloroquinoxaline $N$-oxide was found to suit for the cascade reaction and successfully restrain the formation of over-oxidized by-product. Symmetric and unsymmetric furans can be prepared by the homo- or cross-coupling of ynamides. Furthermore, we applied this methodology for the intramolecular transformation of di-ynamides resulting in a variety of valuable macrocyclic furan-containing frameworks.

\begin{itemize}
\item A) Intermolecular cycloaddition of $\alpha$-oxo gold carbene accessed \textit{via} alkyne oxidation (Zhang)
\item B) Gold-catalyzed ynamide self-dimerization (Skrydstrup)
\item C) Gold-catalyzed oxidative [2+2+1] annulation of ynamides (this work)
\end{itemize}

\underline{Scheme 1.} Gold-catalyzed oxidative cyclization with ynamide starting materials
5.2 Results and Discussion

5.2.1 Optimization of the Reaction Conditions

Initially, we focused on the reaction of ynamide 2a with different N-oxides using 5 mol% of tBuXPhosAuCl/AgNTf$_2$ at 70 °C. As shown in Table 1, pyridine N-oxide 1a or quinoline N-oxides 1b and 1c delivered no furan product 3a even if the N-oxide reagents were slowly added to the reaction mixture (entry 1-3). To our delight, 2, 3-diphenyl quinoxaline N-oxide 1d produced the furan 3a in 63 % yield accompanied by 24 % of 3a' resulting from ynamide over-oxidation (entry 4). This revealed that the less nucleophilic N-oxides can prevent from the over-oxidation of ynamides. Following this principle, the chloro-substituted quinoxaline N-oxide 1e was tested, the formation of 3a' was almost suppressed and 3a was gained in 84 % yield (entry 5). In order to increase the yield further, some acids were screened. 0.5 equiv. MsOH led to 61 % yield of furan and the by-product of ynamide hydrolysis (entry 6). Anhydrous acids, such as HBF$_4$·Et$_2$O and HCl dioxane solevent gave rise to 89% yield of 3a (entry 7-8). 0.1 equiv. HCl dioxane solevent affored the furan in 90 % isolated yield (entry 9). Other common gold catalysts in combination with the acid did not improve the reaction (entry 10-12). The controlled experiment presented the reaction could not proceed without gold catalyst (entry 13).

[a] Reaction conditions: 2a (0.3 mmol), N-oxide reagent (0.1 mmol), additives and 5 mol% catalyst in 1 ml 1,2-DCE at 70 °C for 30 mins. [b] Measured by ¹H NMR with dibromomethane as the internal standard. [c] Methanesulfonic acid. [d] 4 M HCl in dioxane. [e] Isolated yield.

### 5.2.2 Mechanism Investigation

![Scheme 2](image)

Remarkably, while the presumed α-oxo gold carbene, produced by 2,3-dichloroquinoxaline N-oxide, performed the furan in the excellent selectivity, the gold carbene species generated via pyridine N-oxides could not promote the furan
formation with an excess of ynamide. The distinct result suggests that the actual intermediate is not a free carbene species. Instead, the addition of the leaving \( N \)-heterocycle to the \( \alpha \)-oxo gold carbene takes place (Scheme 2).\(^{[12]}\) The so formed gold carbenoid I with weakly nucleophilic quinoxaline could facilitate the selective formation of furan and disable the reaction with quinoxaline \( N \)-oxide, whereas the gold carbenoid II can not be trapped by the ynamide due to the stronger coordinating pyridine which reduces the reactivity of the carbenoid.

### 5.2.3 Scope and Limitation

With the optimized condition in hand, a vast range of aryl substituted ynamides was employed to prepare symmetric furans (Table 2). The reaction tolerated various functional groups, including methoxy (3c), halogen (3d, 3j, 3m), trifluoromethyl (3e), ester groups (3h) and a dioxane moiety (3n). Due to the steric effect, low yields were obtained with bulky 3, 5-disubstituted phenyl ynamides (3k, 3l). Alkyl substituted ynamides decomposed under the oxidizing condition. Next we varied the amide moiety of the ynamide. A set of protecting groups and substituents at the R-position were checked (3r-t). Both mesyl (3r) and an easily removable nosyl group (3t) were well compatible. The molecular structure of 3a was confirmed by single crystal X-ray diffraction.\(^{[13]}\)

[a] Reaction conditions: 1e (0.1 mmol), 2 (0.3 mmol), 10 mol% HCl solvent (4 M HCl in dioxane), and 5 mol% tBuXPhosAuCl /AgNTf₂ at 70 °C for 30 mins in 1 ml 1,2-DCE. [b] Isolated yields.

In order to enhance the synthetic utility, our attention was turned to the construction of unsymmetrical furan skeletons as well (Table 3). The reaction of quinoxaline N-oxide 1e, a threefold excess of ynamide 2, and another more nuleophilic ynamide 2’ under the standard condition could delivered unsymmetrical furans by the cross-coupling of different ynamides. Ynamides containing different aryl substituents and protecting groups were tested together to suit the principle. A whole series of unsymmetrical furans 4 were obtained in moderate to good yields with well tolerance to diverse functional groups (4a-h). Besides of sulfamides, the transformation of an oxazolidinone-derived ynamide together with ynamide 2a also afforded the product 4i in 21 % yield. However, the cross dimerization of aryl substituted ynamide with alkyl substituted ynamides failed to produce the furan.

[c] Ynamide 2e was used.
Macrocyclic furan derivatives widely exist in natural products, such as lophotoxin and bipinnatin.\[^{14}\] The conventional entry to macrocyclic furans mainly focused on the furan synthesis inside of a macrocycle. As a complementary strategy, this methodology was applied in the intramolecular macrocyclization of di-ynamides to construct furan motifs incorporated in macrocyclic systems during the macrocyclization step (Table 4). The use of 10 mol% gold catalyst and diluted concentration (0.01 M) led to the strained 10-membered ring 6a in 20% yield and 11- to 13-membered rings in good yields (6b-e). The solid state structure of 6b was disclosed by X-ray diffraction.\[^{13}\] The synthesis of unsymmetric macrocyclic furan 6f was accomplished as well. In addition, the efficient approach to macrolactone 6g from Boc-protected 2-aminoethanol and 4-aminobutanoic acid was demonstrated (Scheme 3).

**Table 4. Intramolecular macrocyclization of di-ynamides.**\[^{[a,b]}\]
In summary, gold-catalyzed oxidative [2+2+1] cycloaddition of ynamides with 2, 3-dichloroquinoxaline N-oxide has been disclosed. A whole series of densely substituted symmetric and asymmetric furans was prepared with excellent tolerance to diverse functional groups. The method was further employed to the intramolecular annulation of di-ynamides, enabling the convergent assembly of valuable macrocyclic furan derivatives.

Scheme 3. Application in the synthesis of macrolactone.

5.3 Summary

In summary, gold-catalyzed oxidative [2+2+1] cycloaddition of ynamides with 2, 3-dichloroquinoxaline N-oxide has been disclosed. A whole series of densely substituted symmetric and asymmetric furans was prepared with excellent tolerance to diverse functional groups. The method was further employed to the intramolecular annulation of di-ynamides, enabling the convergent assembly of valuable macrocyclic furan derivatives.

5.5 Experimental Section

**General information:** Chemicals were purchased from commercial suppliers and used as delivered. The pyridine N-oxide 1a and quinoline N-oxides 1b, 1c are bought from SigmaAldrich. Quinoxaline N-oxides 1d, 1e and ynamides were prepared according to related literatures.\[1-4\] Deuterated solvents were bought from Euriso-Top. NMR spectra were, if not mentioned otherwise, recorded at room temperature on the following spectrometers: Bruker Avance-III-300, Bruker Avance DRX-300, Bruker-Avance DRX-500 and Bruker Avance-III-500. Chemical shifts are given in ppm and coupling constants in Hz. The following abbreviations were used for $^1$H
NMR spectra to indicate the signal multiplicity: s (singlet), brs (broad singlet), d (doublet), t (triplet), q (quartet), quint (quintet), sext (sextet), sept (septet) and m (multiplet) as well as combinations of them. When combinations of multiplicities are given the first character noted refers to the biggest coupling constant. All $^{13}$C NMR spectra were measured with $^1$H-decoupling. The multiplicities mentioned in these spectra [s (singlet, quaternary carbon), d (doublet, CH-group), t (triplet, CH$_2$-group), q (quartet, CH$_3$-group)] were determined by DEPT135 and HSQC spectra. Mass spectra (MS and HRMS) were determined at the chemistry department of the University of Heidelberg under the direction of Dr. J. Gross. EI$^+$-spectra were measured on a JOEL JMS-700 spectrometer. For ESI$^+$-spectra a Bruker ApexQu FT-ICR-MS spectrometer was applied. Infrared Spectroscopy (IR) was processed on an FT-IR Bruker (IF528), IR Perkin Elmer (283) or FT-IR Bruker Vector 22. The solvent or matrix is denoted in brackets. For the most significant bands the wave number ν (cm$^{-1}$) is given. X-ray crystal structure analyses were measured at the chemistry department of the University of Heidelberg under the direction of Dr. F. Rominger on a Bruker Smart CCD or Bruker APEX-II CCD instrument using Mo-Kα-radiation. Diffraction intensities were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using SADABS based on the Laue symmetry of reciprocal space. Heavy atom diffractions were solved by direct methods and refined against F2 with full matrix least square algorithm. Hydrogen atoms were either isotropically refined or calculated. The structures were solved and refined by Dr. F. Rominger using the SHELXTL software package. Gas Chromatography / Mass Spectrometry (GC/MS) spectra were measured on two different hardware systems: 1. HP 5972 Mass Selective Detector, coupled with a HP 5890 SERIES II plus gas chromatograph. 2. Agilent 5975C Mass Selective Detector, coupled with an Agilent 7890A gas chromatograph. In both cases, as a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and helium was used as the carrier gas. Gas Chromatography (GC) was carried out on a HP 5890 SERIES II plus gas chromatograph. As a capillary column, an OPTIMA 5 cross-linked Methyl Silicone column (30 m x 0.32 mm, 0.25 µm) was employed and nitrogen was used as the carrier gas. Melting Points were measured in open glass capillaries in a Büchi melting point apparatus (according to Dr. Tottoli) and were not corrected. Flash Column Chromatography was accomplished using Silica gel 60 (0.04 - 0.063 mm / 230 - 400 mesh ASTM) purchased from Macherey-Nagel or Aluminium.
oxide (neutral or basic) purchased from Macherey-Nagel. As eluents, mixtures of petroleum ether (PE), ethyl acetate (EA), dichloromethane (DCM) and diethylether (Et$_2$O) were used. Analytical Thin Layer Chromatography (TLC) was carried out on precoated Macherey-Nagel POLYGRAM® SIL G/UV254 or POLYGRAM® ALOX N/UV254 plastic sheets. Detection was accomplished using UV-light (254 nm), KMnO$_4$ (in 1.5 M Na$_2$CO$_3$ (aq.)), molybdatophosphoric acid (5 % in ethanol), vanillin/H$_2$SO$_4$ (in ethanol) or anisaldehyde/HOAc (in ethanol). IUPAC names of the compounds described in the experimental section were determined with the program ACDLabs 12.0°.

**Experimental Procedures**

![Experimental Procedures Diagram](image)

A round bottom flask equipped with a magnetic stirrer bar was charged with tBuXPhosAuCl (5 mol%, 3.2 mg), AgNTf$_2$ (5 mol%, 2 mg), and 1,2-DCE (1 ml). The mixture was stirred for 5 minutes at room temperature. Then the ynamide (0.3 mmol) and 2,3-dichloroquinoxaline N-oxide (0.1 mmol, 21.5 mg) and 2.5 mL HCl (4M HCl in dioxane) were added. The reaction was heated at 70 °C for 30 mins. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO$_2$, hexanes/EtOAc) to provide the symmetric furan product. The characterization data of the products are listed in part 3.

![Experimental Procedures Diagram](image)

A round bottom flask equipped with a magnetic stirrer bar was charged with tBuXPhosAuCl (5 mol%, 3.2 mg), AgNTf$_2$ (5 mol%, 2 mg), and 1,2-DCE (1 ml). The mixture was stirred for 5 minutes at room temperature. Then the ynamide 2 (0.3 mmol or 0.4 mmol), another ynamide 2' (0.1 mmol), 2,3-dichloroquinoxaline N-oxide (0.1 mmol) and 2.5 mL HCl (4M HCl in dioxane) were added. The reaction was heated at 70 °C for 1 h. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO$_2$, hexanes/EtOAc) to
provide the unsymmetric furan product. The characterization data of the products are listed in part 3.

A round bottom flask equipped with a magnetic stirrer bar was charged with tBuXPhosAuCl (10 mol%, 6.4 mg), AgNTf₂ (5 mol%, 4 mg), and 1,2-DCE (1 ml). The mixture was stirred for 5 minutes at room temperature. Then the di-ynamide 5 (0.12 mmol) and 2,3-dichloroquinoxaline N-oxide (0.1 mmol) in 9 ml 1,2-DCE were added. The reaction was heated at 70 °C for 30 mins. After cooling to room temperature, the solvent was reduced in vacuo, and the residue was purified by column chromatography (SiO₂, hexanes/EtOAc) to provide the macrocyclic furan compound. The characterization data of the products are listed in part 3.
