# Biological and clinical impact of the immunoglobulin light chain sequence diversity in patients with dominant heart AL amyloidosis

Inauguraldissertation  
zur Erlangung des Doctor scientiarum humanarum (Dr. sc. hum.)  
an der  
Medizinischen Fakultät Heidelberg  
der  
Ruprecht-Karls-Universität

vorgelegt von  
Natalie Berghaus

aus  
Wiesbaden

2023

Dekan: Herr Prof. Dr. Dr. h.c. Hans-Georg Kräusslich  
Doktorvater: Herr Prof. Dr. med. Stefan O. Schönland

## Table of Contents

<b><i>Table of Contents</i></b>	<b>3</b>
<b><i>List of Abbreviations</i></b>	<b>7</b>
<b><i>List of Figures</i></b>	<b>10</b>
<b><i>List of Tables</i></b>	<b>15</b>
<b><i>1 Introduction</i></b>	<b>17</b>
<b>1.1 Immunoglobulins</b>	<b>17</b>
1.1.1 Structure of Human Immunoglobulins	17
1.1.2 B Cell Development	19
1.1.3 Lambda Light Chain Locus	20
1.1.4 Diversity of Immunoglobulins	21
<b>1.2 Monoclonal Gammopathies</b>	<b>22</b>
<b>1.3 Multiple Myeloma</b>	<b>24</b>
1.3.1 Biology of Multiple Myeloma	24
1.3.2 Clinical Presentation and Diagnosis of Multiple Myeloma	28
<b>1.4 AL Amyloidosis</b>	<b>29</b>
1.4.1 Forms of Amyloidosis	29
1.4.2 Clinical Presentation and Diagnosis of AL Amyloidosis	31
1.4.3 Pathological Effect of Light Chains and Fibrils	35
1.4.4 Pathway of Fibril Formation	36
1.4.5 Fibril Structure	38
<b>1.5 Aim of the Study</b>	<b>40</b>
<b><i>2 Material and Methods</i></b>	<b>41</b>
<b>2.1 Material</b>	<b>41</b>
2.1.1 Equipment and Consumables	41
2.1.2 Chemicals and Enzymes	42
2.1.3 Buffer	43
2.1.4 Oligonucleotides	44
2.1.5 Kits and Standards	45
2.1.6 Next-Generation Sequencing	45
2.1.7 Counterprograms and Websites	46
<b>2.2 AL Amyloidosis Patients and Samples</b>	<b>47</b>
<b>2.3 Multiple Myeloma Patients and Samples</b>	<b>48</b>

<b>2.4 Clinical Characteristics of the Cohorts</b>	<b>48</b>
<b>2.5 Bone Marrow Sample Preparation</b>	<b>49</b>
2.5.1 Isolation of Mononuclear Cells	49
2.5.2 CD138-Cell Sorting	50
2.5.3 Cytospins	51
2.5.4 Cell-Pellets	51
<b>2.6 Molecular Biological Methods</b>	<b>51</b>
2.6.1 Isolation of Genomic DNA and RNA	51
2.6.2 DNA and RNA Concentration Measurement	52
2.6.3 Reverse Transcriptase Reaction	52
2.6.4 Polymerase-Chain Reaction	52
2.6.5 Analytic Gel-Electrophoresis	54
2.6.6 PCR-Product Purification	54
<b>2.7 DNA Sanger Sequencing</b>	<b>54</b>
<b>2.8 Next-Generation Sequencing</b>	<b>54</b>
2.8.1 AL Amyloidosis Patients	54
2.8.2 Multiple Myeloma Patients	56
<b>2.9 Analysis</b>	<b>56</b>
2.9.1 Sanger Sequencing Analysis	56
2.9.2 Next-Generation Sequencing Analysis	56
2.9.3 IGL Family Assignment	57
2.9.4 Mutation Analysis	57
2.9.5 Amino Acid Composition Analysis	58
2.9.6 Biophysical Parameter Analysis	58
2.9.7 Statistical Analysis and Data Visualization	59
<b>3 Results</b>	<b>60</b>
<b>3.1 Clinical Characteristics of the Cohorts</b>	<b>60</b>
<b>3.2 Multiple Myeloma Sample Composition</b>	<b>63</b>
<b>3.3 IGL Family Distribution</b>	<b>65</b>
3.3.1 IGLV Family and Subfamily Distribution	65
3.3.2 IGLJ and IGLC Family Distribution	69
3.3.3 Composition of the IGLV, IGLJ, and IGLC Segments	70
<b>3.4 IGLV2-14</b>	<b>72</b>
3.4.1 Subgroup Analysis	72
3.4.2 Mutation Frequency and Count	73
3.4.3 Sequence Alignment	75
3.4.4 Amino Acid Composition	78

3.4.5 Biophysical Parameters	80
3.4.6 Summary IGLV2-14	82
<b>3.5 IGLV3-1</b>	<b>83</b>
3.5.1 Subgroup Analysis	84
3.5.2 Mutation Frequency and Count	85
3.5.3 Sequence Alignment	86
3.5.4 Amino Acid Composition	89
3.5.5 Biophysical Parameters	91
3.5.6 Summary IGLV3-1	92
<b>3.6 IGLV3-21</b>	<b>94</b>
3.6.1 Subgroup Analysis	95
3.6.2 Verification of the AL IGLV3-21 Sequences and Subfamily Assignment through a Next-Generation Sequencing Approach	96
3.6.3 Analysis for Lack of N-terminal Coverage of IGLV3-21 AL Sequences through a Next-Generation Sequencing Approach	101
3.6.4 Sequence Alignment	104
3.6.5 Summary IGLV3-21	107
<b>3.7 IGLV6-57 and IGLV2-23</b>	<b>109</b>
3.7.1 Subgroup Analysis	109
3.7.2 Mutation Frequency and Count	111
3.7.3 Sequence Alignment	113
3.7.4 Amino Acid Composition	116
3.7.5 Biophysical Parameters	118
3.7.6 Summary IGLV6-57 and IGLV2-23	120
<b>3.8 Summary of Common IGLV Subfamilies</b>	<b>122</b>
<b>3.9 Rare IGLV Subfamilies</b>	<b>127</b>
3.9.1 IGLV1-40	127
3.9.2 IGLV1-44	127
3.9.3 IGLV1-47	129
3.9.4 IGLV1-51	129
3.9.5 IGLV2-8	129
3.9.6 IGLV2-11	129
3.9.7 IGLV3-19	130
3.9.8 IGLV3-25	130
3.9.9 IGLV7-46	130
3.9.10 IGLV8-61	130
<b>3.10 Summary of Rare IGLV Subfamilies</b>	<b>131</b>
<b>4 Discussion</b>	<b>133</b>

<b>4.1 How to be Sure to Sequence the Amyloidogenic Clone?</b>	<b>134</b>
4.1.1 Verification Steps	134
4.1.2 Challenges	135
<b>4.2 Discrimination between Amyloidogenic and Non-Amyloidogenic Light Chains</b>	<b>136</b>
4.2.1 IGLV Subfamily Usage	137
4.2.2 Mutation Frequency and Count	139
4.2.3 Mutation Hotspots and Sequence Characteristics	141
4.2.4 Biophysical Parameters	143
<b>4.3 Influence of a Potential Heavy Chain Binding Partner or dFLC &gt;180 mg/L</b>	<b>146</b>
<b>4.4 Prediction of Amyloidogenicity</b>	<b>148</b>
<b>4.5 Outlook</b>	<b>150</b>
<b>5 Summary</b>	<b>152</b>
<b>6 Zusammenfassung</b>	<b>154</b>
<b>7 Literature</b>	<b>156</b>
<b>8 Own Contribution to Data Collection, Analysis and Publications</b>	<b>172</b>

## List of Abbreviations

AA	Amino acid
AApoAI	Apolipoprotein AI amyloidosis
AFib	Fibrinogen $\alpha$ chain amyloidosis
AGG	Beta sheet aggregation tendency value
AL	AL amyloidosis
AL < dFLC	A subgroup of light chain sequences corresponding to AL amyloidosis patients with a dFLC value <180 mg/L
AL > dFLC	A subgroup of light chain sequences corresponding to AL amyloidosis patients with a dFLC value >180 mg/L
AL HC	A subgroup of light chain sequences corresponding to AL amyloidosis patients with detectable clonal heavy chain in serum
AL no HC	A subgroup of light chain sequences corresponding to AL amyloidosis patients without detectable clonal heavy chain in serum
AL_D	AL amyloidosis patients with no dominant heart, kidney and heart, and kidney involvement
AL_H	AL amyloidosis patients with dominant heart involvement
AL_HK	AL amyloidosis patients with dominant heart and kidney involvement
AL_HTX	AL amyloidosis patients who received a heart transplant
AL_K	AL amyloidosis patients with dominant kidney involvement
AL+MM	AL amyloidosis patients who were also diagnosed with multiple myeloma
ALECT2	Leukocyte chemotactic factor 2 amyloidosis
ALZ	Zentrallabor-Analysezentrum University Hospital Heidelberg
Amp	Amplification
ANS	Autonomic nerve system
AP	Alkaline phosphatase
ATTRwt	Wild-type transthyretin amyloidosis
A $\beta$ 2m	$\beta$ 2-microglobulin dialysis-related amyloidosis
BM	Bone marrow
BNP	B natriuretic peptide
C	Constant segment
CA	Chromosomal aberrations
CCND1	Cyclin D1
CCND3	Cyclin D3
cDNA	Complementary deoxyribonucleic acid
CDR	Complementary-determining regions
CH	Constant domain heavy chain
Chi	Significance level was calculated using a two-tailored Pearson-Chi-Quadrat-test
CL	Constant domain light chain
CLIA	Chemiluminescence-immunoassay
CT	Computed tomography
cTNT	Cardiac troponin T

D	Diversity segment
Del	Deletion
dFLC	Difference between disease-associated and uninvolved circulation-free light chains
DNA	Deoxyribonucleic acid
DPD	<sup>99m</sup> Tc-labelled 3,3-diphosphono-1,2-propanodicarboxylic acid
ECLIA	Electrochemiluminescence-immunoassay
eGFR	Estimated glomerular filtration rate
Fab	Antigen-binding fragments of an antibody
Fac	Crystallizable fragment of an antibody
FGFR3	Fibroblast growth factor 3
Fischer	Significance level was calculated using a Fischer test
FISH	Fluorescence in situ hybridization
FL	Focal lesion
FR	Framework region
GC	Germinal center
GFR CKD-EPI	Calculation of the glomerular filtration rate using the formula established by the Chronic Kidney Disease Epidemiology Collaboration
GMMG	German-speaking Myeloma Multicenter Group
GRAVY	Grand average of hydropathicity value
GTC	Guanidinium thiocyanate
HC	Heavy chain
hsTNT	Heart-associated troponin T
HY	Hyperdiploid
IFE	Immunofixation electrophoresis in serum
Ig	Immunoglobulin
IGH	Immunoglobulin heavy chain
IGK	Immunoglobulin kappa light chain
IGL	Immunoglobulin lambda light chain
J	Joining segment
L1	Lumbar spine
LC	Light chain
LOH	Loss of heterozygosity
MCL	Molekular-cytogenetisches Labor University Hospital Heidelberg
MDE	Myeloma defining events
Median	Significance level was calculated using a median test
MGUS	Monoclonal gammopathy of undermined significance
MM	Multiple myeloma
MM < dFLC	A subgroup of light chain sequences corresponding to multiple myeloma patients with a dFLC value <180 mg/L
MM > dFLC	A subgroup of light chain sequences corresponding to multiple myeloma patients with a dFLC value >180 mg/L
MM HC	A subgroup of light chain sequences corresponding to multiple myeloma patients with detectable clonal heavy chain in serum

MM no HC	A subgroup of light chain sequences corresponding to multiple myeloma patients without detectable clonal heavy chain in serum
MMSET	Multiple myeloma SET domain
MP_NGS_PCR	Next-generation sequencing approach addressing AL amyloidosis IGLV3-21 samples based on polymerase-chain-reaction products generated using the VLKL12a_Huhn, VLKL3c_Huhn, VLKL4a_Huhn, VLKL7a_Huhn and JLHD123_rv oligonucleotides
M-protein	Monoclonal protein
MRI	Magnetic resonance imaging
Mw	Molecular weight
N_NGS_PCR	Next-generation sequencing approach addressing AL amyloidosis IGLV3-21 samples based on polymerase-chain-reaction products generated using the VLKL3_A_fw_NB and JLHD123_rv oligonucleotides
NA	Not available
NGS	Next-generation sequencing
NMR	Nuclear magnetic resonance
NT-proBNP	N-terminal provisional brain natriuretic peptide
PC	Plasma cells
PCL	Plasma cell leukemia
PCR	Polymerase-chain-reaction
pI	Isoelectric point
PIC	Physician in charge
PNS	Peripheral nerve system
PYP	<sup>99m</sup> Tc-labeled pyrophosphate
RNA	Ribonucleic acid
RR	Relative risk
SBP	Systolic blood pressure
Sequence_A	Sequences with the highest percentage $\geq 1$ % in the next-generation sequencing approaches, sequences are named in descending alphabetic order
SMM	Smoldering multiple myeloma
SNC	Single nucleotide variant
SOP	Standard operation procedure
STAT3	Signal transducer and activator of transcription 3
t-test	Significance level was calculated using a two-tailed t-test
U-test	Significance level was calculated using a two-tailed Mann-Whitney U-test
V	Variable segment
VH	Variable domain heavy chain
VL	Variable domain light chain
X	Not clearly determined amino acid
$\Delta$ pI	Difference between the isoelectric point of the patient-derived light chain and a respective reference sequence

## List of Figures

Figure 1. A) Schematic structure of an IgG antibody. B) Human immunoglobulin chain, domain structure, structural labels as well as sequence definition for the heavy chain and light chain classes. ....	18
Figure 2. Schema of the B cell differentiation and the regulation of the immunoglobulin gene rearrangements in the pre-B cell. ....	20
Figure 3. Evolution of plasma cell dyscrasias. ....	24
Figure 4. Multi-regional evolution in a multiple myeloma patient. ....	27
Figure 5. Characteristic osteolysis and plasma cell increase in multiple myeloma patients. ....	28
Figure 6. Organ involvement in systemic AL amyloidosis. ....	33
Figure 7. Photos of two heart transplants from AL amyloidosis patients. ....	36
Figure 8. Kinetics of fibril formation in vitro. ....	37
Figure 9. Location of the mutations in known AL amyloid fibrils and natively folded VL domains. ....	39
Figure 10. Polymerase chain reaction scheme for sequencing full-length lambda light chains with associated oligonucleotides. ....	53
Figure 11. Comparison of the IGLV family and subfamily distribution between the AL amyloidosis and the multiple myeloma cohort as well as between the heart and heart and kidney organ tropism in AL amyloidosis. ....	66
Figure 12. Comparison of the IGLV subfamily distribution between the AL amyloidosis and the multiple myeloma cohort and the presence or absence of a clonal heavy chain or a dFLC >180 mg/L. ....	68
Figure 13. Sequence sections of IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences. ....	77
Figure 14. Comparison between the amino acid probability in the CDR3 region of IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences. ....	78
Figure 15. Comparison of the overall amino acid percentage of threonine, asparagine, and serine in the IGLV2-14 light chain sequences between the AL amyloidosis organ tropism and the multiple myeloma cohort. ....	79
Figure 16. Comparison of the overall amino acid percentage of asparagine and threonine in IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences with respect to the presence or absence of a clonal heavy chain or a dFLC >180 mg/L. ....	80
Figure 17. Sequence sections of IGLV3-1 assigned AL amyloidosis and multiple myeloma light chain sequences. ....	88
Figure 18. Comparison between the amino acid probability in the CDR3 region of IGLV3-1 assigned AL amyloidosis light chain sequences in the context of the absence or presence of a clonal heavy chain in serum. ....	89
Figure 19. Comparison of the overall amino acid percentage of arginine, serine, and valine in IGLV3-1 assigned AL amyloidosis and multiple myeloma light chain sequences. ....	90
Figure 20. Comparison of the overall amino acid percentage of serine and asparagine between IGLV3-1 assigned AL amyloidosis and multiple myeloma sequences with respect to the presence or absence of a clonal heavy chain. ....	91
Figure 21. Section of an electropherogram of a sequencing reaction leading to one main sequence and several subsequences. ....	94
Figure 22. Sequence alignment of the Sanger sequence and the sequence with the highest percentage in the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples for FOR104_pC and FOR176. ....	98

Figure 23. FOR163 sequence alignment of the sequence generated by Sanger sequencing and the sequence with the highest percentage in the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples. ....	99
Figure 24. FOR113 sequence alignment of the sequence generated by Sanger sequencing and the sequence with the highest percentage in the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples. ....	100
Figure 25. Sequence alignment of the IGLV3-21 sequence with the highest percentage in the MP_NGS_PCR approach and the IGLV3-21 sequences in the N_NGS_PCR approach. ....	103
Figure 26. Sequence sections of IGLV3-21 assigned AL amyloidosis and multiple myeloma light chain sequences. ....	106
Figure 27. Sequence sections of IGLV3-21 AL amyloidosis sequences stratified for the presence or absence of a clonal heavy chain in serum. ....	107
Figure 28. Sequence sections of IGLV6-57 assigned AL amyloidosis and multiple myeloma light chain sequences and IGLV2-23 assigned multiple myeloma light chain sequences. ....	114
Figure 29. Sequence section of IGLV6-57 assigned AL amyloidosis and multiple myeloma light chain sequences and IGLV2-23 assigned multiple myeloma light chain sequences with respect to additional charges. ....	115
Figure 30. Comparison of the overall isoleucine and lysine percentage between IGLV6-57 assigned AL amyloidosis light chain sequences corresponding to patients with dominant heart or dominant heart and kidney involvement. ....	117
Figure 31. Comparison of the overall amino acid percentage of serine and aspartic acid between IGLV6-57 assigned AL amyloidosis light chain sequences with respect to the presence or absence of a clonal HC or a dFLC >180 mg/L. ....	118
Figure 32. Sequence sections of IGLV1-44 assigned AL amyloidosis and multiple myeloma light chain sequences. ....	128
Figure 33. Correlation of the percentage of the detected IGLV subfamilies in the AL amyloidosis and multiple myeloma cohort, with the (A) grand average of hydropathicity score, (B) isoelectric point, (C) AGG parameter and (D) the molecular weight of the respective IGLV reference sequence. ....	145
Figure 34. Risk stratification of monoclonal gammopathy of undefined significance / smoldering multiple myeloma / multiple myeloma patients for the progression towards AL amyloidosis based on light chain sequencing results. ....	149
Supplementary Information Figure 1. Establishment of a PCR for full-length light chain sequencing. ....	177
Supplementary Information Figure 2. Internal revised quality document for the preparation of bone marrow using a density gradient centrifugation. ....	178
Supplementary Information Figure 3. Internal revised quality document for the CD138 <sup>+</sup> cell sorting following the Stem cell protocol and using a robotry. ....	179
Supplementary Information Figure 4. Internal revised quality document for the cell counting using the Countess cell counter. ....	180
Supplementary Information Figure 5. Internal revised quality document for the preparation of cytopspins for the cytogenetic analysis if myeloma cells. ....	181

Supplementary Information Figure 6. Internal revised quality document for the material division of amyloidosis samples.....	182
Supplementary Information Figure 7. Internal revised quality document for concentration determination and gel electrophoresis using the tapestation system.....	183
Supplementary Information Figure 8. Sequence comparison between MM103 IGLV2-14 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	186
Supplementary Information Figure 9. Sequence comparison between MM129 IGLV2-14 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	187
Supplementary Information Figure 10. Sequence comparison between MM130 IGLV2-14 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	188
Supplementary Information Figure 11. Sequence comparison between MM136 IGLV2-14 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	189
Supplementary Information Figure 12. Sequence alignment of IGLV2-14 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences.....	190
Supplementary Information Figure 13. Sequence alignment of IGLV2-14 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences.....	191
Supplementary Information Figure 14. Sequence comparison between MM120 IGLV3-1 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	193
Supplementary Information Figure 15. Sequence alignment of IGLV3-1 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences.....	194
Supplementary Information Figure 16. Sequence alignment of IGLV3-1 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences.....	195
Supplementary Information Figure 17. Sequence comparison between MM106 IGLV3-21 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	197
Supplementary Information Figure 18. Sequence comparison between MM111 IGLV3-21 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	198
Supplementary Information Figure 19. Sequence comparison between MM111 IGLV3-21 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.....	199
Supplementary Information Figure 20. Sequence alignment of the Sanger sequence and the sequence with the highest percentage in the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples for FOR136 and FOR177.....	200
Supplementary Information Figure 21. Sequence alignment of the FOR169 Sanger sequence and the sequence with the highest percentage in the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples.....	200
Supplementary Information Figure 22. Sequence alignment of the FOR113, FOR136, FOR163 and FOR169 sequences with the highest percentage in the two IGLV3-21 next-generation sequencing experiments.....	201
Supplementary Information Figure 23. Sequence comparison of the FOR113, FOR136, FOR163 and FOR169 sequences with the highest percentage in the N <sub>NGS_PCR</sub> approach and corresponding sequences in the MP <sub>NGS_PCR</sub> approach.....	202
Supplementary Information Figure 24. Sequence alignment of IGLV3-21 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences.....	203

Supplementary Information Figure 25. Sequence alignment of IGLV3-21 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences. ....	204
Supplementary Information Figure 26. Sequence comparison between MM112 IGLV6-57 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	205
Supplementary Information Figure 27. Alignment of sequence sections given by the bioinformatic analysis of the bulk RNA sequencing approach of M107. ....	206
Supplementary Information Figure 28. Alignment of sequence sections given by the bioinformatic analysis of the bulk RNA sequencing approach of M132. ....	207
Supplementary Information Figure 29. Sequence alignment of IGLV6-57 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences. ....	208
Supplementary Information Figure 30. Sequence alignment of IGLV6-57 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences. ....	209
Supplementary Information Figure 31. Sequence alignment of IGLV2-23 assigned multiple myeloma amino acid light chain sequences. ....	210
Supplementary Information Figure 32. Sequence alignment of IGLV2-23 assigned multiple myeloma cDNA light chain sequences. ....	211
Supplementary Information Figure 33. Sequence alignment of IGLV1-40 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences. ....	213
Supplementary Information Figure 34. Sequence alignment of IGLV1-40 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences. ....	214
Supplementary Information Figure 35. Sequence comparison between MM104 IGLV1-40 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	215
Supplementary Information Figure 36. Sequence Alignment of IGLV1-44 assigned multiple myeloma light chain sequences with an additional sequence in the bioinformatic analysis of the bulk RNA sequencing approach. ...	216
Supplementary Information Figure 37. Sequence comparison between MM116 IGLV1-44 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	217
Supplementary Information Figure 38. Sequence comparison between MM119 IGLV1-44 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	218
Supplementary Information Figure 39. Sequence comparison between MM137 IGLV1-44 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	219
Supplementary Information Figure 40. Sequence comparison between MM141 IGLV1-44 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	220
Supplementary Information Figure 41. Sequence alignment of IGLV1-44 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences. ....	221
Supplementary Information Figure 42. Sequence alignment of IGLV1-44 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences. ....	222
Supplementary Information Figure 43. Sequence alignment of IGLV1-47 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences. ....	223
Supplementary Information Figure 44. Sequence alignment of IGLV1-47 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences. ....	223

Supplementary Information Figure 45. Sequence alignment of IGLV1-51 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences. ....	224
Supplementary Information Figure 46. Sequence alignment of IGLV1-51 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences. ....	225
Supplementary Information Figure 47. Sequence alignment of IGLV2-8 assigned AL amyloidosis amino acid light chain sequences. ....	225
Supplementary Information Figure 48. Sequence alignment of IGLV2-8 assigned AL amyloidosis cDNA light chain sequences. ....	226
Supplementary Information Figure 49. Sequence alignment of the IGLV2-11 assigned MM127 multiple myeloma amino acid light chain sequence. ....	226
Supplementary Information Figure 50. Sequence alignment of the IGLV2-11 assigned MM127 multiple myeloma cDNA light chain sequence. ....	227
Supplementary Information Figure 51. Sequence comparison between MM127 IGLV2-11 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	228
Supplementary Information Figure 52. Sequence alignment of IGLV3-19 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences. ....	229
Supplementary Information Figure 53. Sequence alignment of IGLV3-19 assigned AL amyloidosis and multiple myeloma cDNA light chain sequences. ....	230
Supplementary Information Figure 54. Sequence comparison between MM128 IGLV3-19 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach. ....	231
Supplementary Information Figure 55. Sequence alignment of the IGLV3-25 assigned AL amyloidosis and multiple myeloma amino acid light chain sequence. ....	232
Supplementary Information Figure 56. Sequence alignment of the IGLV3-25 assigned AL amyloidosis and multiple myeloma cDNA light chain sequence. ....	232
Supplementary Information Figure 57. Sequence alignment of the IGLV7-46 assigned MM113 multiple myeloma amino acid light chain sequence. ....	233
Supplementary Information Figure 58. Sequence alignment of the IGLV7-46 assigned MM113 multiple myeloma cDNA light chain sequence. ....	233
Supplementary Information Figure 59. Sequence alignment of the IGLV8-61 assigned FOR229 AL amyloidosis amino acid light chain sequence. ....	234
Supplementary Information Figure 60. Sequence alignment of the IGLV8-61 assigned FOR229 AL amyloidosis cDNA light chain sequence. ....	234

## List of Tables

Table 1. Immunoglobulin classes and their approximate percentage of the total immunoglobulins in the adult serum.....	19
Table 2. Potential Homo sapiens IGLV genomic repertoire.....	21
Table 3. Primary molecular cytogenetic classification of multiple myeloma.....	26
Table 4. Most common forms of systemic amyloidosis.....	30
Table 5. Overview of the most commonly used staging systems in AL amyloidosis.....	34
Table 6. Equipment.....	41
Table 7. Consumables.....	42
Table 8. Chemicals and enzymes.....	42
Table 9. Buffer.....	43
Table 10. Oligonucleotides.....	44
Table 11. Kits and standards.....	45
Table 12. Next-generation sequencing reagents and kits.....	45
Table 13. Computer programs and Websites.....	46
Table 14. Overview of the clinical characteristics evaluated in this study, who collected them, the reference areas, and the analysis methods used.....	49
Table 15. Comparison of CD138 <sup>+</sup> cell-sorting and the main clone in the FISH analysis of AL amyloidosis patients.....	61

# 1 Introduction

## 1.1 Immunoglobulins

Concerning the human immune system, a distinction must be made between the inborn and the acquired, or so-called adaptive, immune system. The adaptive immune system is characterized by a rapidly increased immune response which is triggered as soon as renewed contact with the antigen occurs. This effect can be described as immunogenetic memory and depends on antigen recognition and the specificity of the immunological response (Marshall et al. 2018). The cell types most responsible for the adaptive immune system are lymphocytes, particularly B and T cells with their effector molecules (Kamradt and Ferrari-Kühne 2011). A single B cell that differentiates into an Ig-producing plasma cell produces each immunoglobulin (Ig) molecule. Ig recognize antigens in their native state on the surface of foreign bodies and trigger elimination processes like cell lysis or phagocytosis. T cells recognize processed antigens which are presented as peptides by the highly polymorphic major histocompatibility proteins (Lefranc 2014; Lefranc and Lefranc 2020). These biological functions of B and T cells are accompanied by the need for a large diversity of their antigen receptors. A healthy individual's potential antigen receptor repertoire is about  $2 \times 10^{12}$  different Ig and T cell receptors. Here, the number of B and T cells an organism is genetically limited to produce is the primary limiting factor (Lefranc and Lefranc 2020).

### 1.1.1 Structure of Human Immunoglobulins

In 1972, Gerald Edelman and Rodney Porter received the Nobel Prize in physiology and medicine for their investigations of the Ig structure (PressRelease\_NobelPrize.org 1972). They were the first who were able to resolve the different fragments (Fab, Fc), the characteristic Y-like shape, and the two-chain structure (**Figure 1**) (Edelman 1959; Porter 1959; Wilson and Stanfield 2021).

Addressing the two-chain structure, the Ig consists of two identical light chains (LC) with about 25 kDa and two identical heavy chains (HC) with 50 – 70 kDa. The HCs can be classified into H-mu, H-delta, H-gamma, H-alpha, and H-epsilon, and the LCs into kappa and lambda. (Lefranc and Lefranc 2020; Schroeder and Cavacini 2010). Structurally, LCs can be separated further into two domains, one variable domain (VL) comprising a variable (V) region and a joining (J) region, and a constant domain (CL). A HC also consists of a variable domain (VH) comprising a V, a J, and an additional diversity (D) region, as well as three or four constant domains (CH) (**Figure 1**) (Lefranc and Lefranc 2020; Schroeder and Cavacini 2010).

Further, the V regions comprise three complementary-determining regions (CDR) which are solvent-exposed and form the antigen-binding site (Kamradt and Ferrari-Kühne 2011; Lefranc and Lefranc 2020; Schroeder and Cavacini 2010). This goes together with the fact that CDRs are characterized as highly variable sequence regions. Especially the CDR3 region is defined as highly variable and extends over the C-terminal end of the V region, the complete D region, and the N-terminal end of the J region. Overall, the CDR regions are framed by four stable "frame" regions (FR) (Schroeder and Cavacini 2010).

Another way to describe an Ig, is to divide it into two antigen-binding fragments (Fab) and one crystallizable fragment (Fc). The two Fab fragments are characterized by their antigen recognition and binding function and include a complete LC, the VH, and one part of the CH (Schroeder and Cavacini 2010). The Fc fragment was also characterized by Porter, who digested a rabbit antibody with papain and was able to crystallize one of the three fragments (Porter 1959).

Ig are expressed in different forms: as membrane proteins, on the surface of mature and memory B cells, as part of the B cell receptor, or as Ig secreted by plasma cells (Lefranc and Lefranc 2020). The secreted Ig can be divided into five different classes based on their distinct HC: IgM, IgD, IgG, IgA, and IgE. They differ in their physicochemical properties, antigenic

determinants, biological functions, and effector properties as well as their abundance in the serum of a healthy individual (**Table 1**) (Lefranc and Lefranc 2020).

**Table 1. Immunoglobulin classes and their approximate percentage of the total immunoglobulins in the adult serum.** Percentage of the Immunoglobulin subclasses in the class: IgG1: 70 – 80 %, IgG2: 18 – 23 %, IgG3: 6 – 8 %, IgG4: 2 – 6 %, IgA1: 90 %, IgA2: 10 %. ### 1.1.2 B Cell Development

In humans, B cell development starts from hematopoietic stem cells in the bone marrow (**Figure 2**). Here, the rearrangement of the immunoglobulin heavy chain (*IGH*) *D* and *J* locus of the Pro-B cell takes place. Afterward, the rearrangement with the *IGHV* locus allows the Pre-B cell to produce a H-mu chain in the cytoplasm. This H-mu chain is expressed on the surface of the cell with a lambda-like chain. This lambda-like chain forms together with a V-pre-B chain the Pre-B cell receptor (Hieter et al. 1981; Korsmeyer et al. 1981; Lefranc and Lefranc 2020).

For the transition from the Pre-B cell receptor towards an immature B cell, the productive rearrangement of the Ig-kappa (*IGK*) or Ig-lambda (*IGL*) locus is required. In this context, the Pre-B cell receptor induces a signal which inhibits further *IGH-V-D* rearrangements and emits a signal to start the LC *V-J* rearrangement. In a first attempt, a productive rearrangement of one chromosome 2 with the kappa locus is strived – if successful, IgM is produced. However, if a productive rearrangement cannot be obtained, a second attempt with the other chromosome 2 and a kappa LC is sought first. If a kappa LC could not be successfully produced with the second chromosome 2 either, a rearrangement on chromosome 22 and the lambda locus is targeted. The kappa/lambda ratio of antibodies in the serum of a healthy individual is approximately 2:1 (Hollis et al. 1989; Lefranc and Lefranc 2020; Schiff et al. 1990).

After a productive rearrangement of the HC and LC loci, the plasma cells expressing functional IgM on the cell surface are called immature B cells. In the next step, B cells with highly autoreactive B cell receptors are sorted out and the remaining cells (transitional B cells) can migrate to the spleen (Eibel et al. 2014). In the spleen, these cells undergo three different transition states, which can be distinguished by the amount of expressed IgM or other surface markers (Chung et al. 2003; Lefranc and Lefranc 2020).

**Figure 2. Schema of the B cell differentiation and the regulation of the immunoglobulin gene rearrangements in the pre-B cell.** Adapted from (Lefranc and Lefranc 2020). ### 1.1.3 Lambda Light Chain Locus

The lambda locus is located on the long arm of chromosome 22q11.2 and spans 1050 kb. It consists of 73 – 74 *IGLV* genes, of which 30 – 36 are potentially functional. Overall, the *IGLV* genes are sorted into 10 *IGLV* families. Additionally, seven to eleven *IGLJ* and *IGLC* genes, of which four are classified as functional, are located on this chromosome. Each *IGLC* gene is preceded by one corresponding *IGLJ* gene (Table 2) (Kawasaki et al. 1997; Lefranc and Lefranc 2020; Schroeder and Cavacini 2010).

**Table 2. Potential Homo sapiens IGLV genomic repertoire.** Adapted from (Lefranc and Lefranc 2020). IGLV = immunoglobulin lambda light chain variable region. ### 1.1.4 Diversity of Immunoglobulins

#### 1.1.4.1 Combinatorial Diversity and Junctional Diversity

As already mentioned, a high degree of diversity is necessary to ensure the biological function of the Ig. Several mechanisms intertwine for this reason, of which one is the possibility to connect several different IGLVJ(D)C segments (combinatorial diversity). This allows the pre-immune repertoire to already achieve a high degree of diversity. This diversity is further enhanced by the enormous variety provided by the  $V(D)J$  joining (junctional diversity). For example, each  $D$  gene has the opportunity to encode six different peptide fragments. These different fragments are created through splicing, translation into different reading frames, and

the possibility to rearrange via inversion or deletion (Schroeder and Cavacini 2010). During this rearrangement process, a hairpin structure between the 5' and 3' ends of the *V* and *J* or *D* segments is created. When this hairpin structure is opened dis-symmetrically, a 3' overhang is created and forms a palindromic extension – the P junction (Schroeder and Cavacini 2010). Moreover, the rearranged segments can also lose one or several nucleotides. In contrast, several nucleotides can also be added or replaced in the original germline sequence by the terminal deoxynucleotidyl transferase, which is template-independent and mostly involves 'G' nucleotides (Lefranc and Lefranc 2020; Schroeder and Cavacini 2010).

These two mechanisms alone allow a possible number of  $10^{10}$  different options, for example, for the HC CDR3 region. These CDR3 regions all differ in length and structure (Schroeder and Cavacini 2010).

#### 1.1.5.2 Somatic Hypermutations

Another mechanism for increasing the Ig diversity are somatic hypermutations which are introduced during B cell maturations in the secondary lymphoid organs (Lefranc and Lefranc 2020). This process takes place during the antigen-dependent stages of differentiation and concerns only the rearranged VJ and D segments. Somatic hypermutations in VJ(D) segments are about  $10^6$  times more frequent than spontaneous mutations in other cells (Lefranc and Lefranc 2020). The introduction of somatic hypermutations is initiated by the activation-induced cytidine deaminase, which induces the deamination from cytosine towards uracil. This uracil is then removed through the uracil deoxyribonucleic acid (DNA) glycosylase and further processed by the DNA base excision repair or DNA mismatch repair system. In the next step, the DNA lesions are repaired, which leads to a transition from cytosine towards thymidine and guanine towards adenine on the opposite strand (Lefranc and Lefranc 2020).

In total, a pre-immune antibody repertoire of  $10^{16}$  different Ig is possible. This is achieved through the connection of the different gene segments, the combinatory effect of the LCs and HCs itself, and the somatic variations in the CDR3 region (Lefranc and Lefranc 2020; Schroeder and Cavacini 2010).

## 1.2 Monoclonal Gammopathies

The diseases classified as monoclonal gammopathies are all characterized by the monoclonal proliferation of at least one single plasma cell. These plasma cells secrete monoclonal proteins (M protein) that present immunologically and electrophoretically homogenous (Group 2003). Based on this protein, other common names are known for this group of diseases: paraproteinaemias, dysproteinaemias, or immunoglobulinopathies (Kyle and Rajkumar 2007).

In a review by the Mayo Clinic in 2006, several associated plasma cell disorders were listed (Kyle and Rajkumar 2007). Here, patients were diagnosed with multiple myeloma (MM) (16.5 %), AL amyloidosis (11.5 %), lymphoproliferative disorders (4 %), smoldering multiple myeloma (SMM) (3 %), Waldenström's macroglobulinemia (2 %) and solitary or extramedullary plasmacytoma (2 %) (others: 6 %) (Kyle and Rajkumar 2007). However, in more than half of the cases, a monoclonal gammopathy of undermined significance (MGUS) (55 %) was diagnosed.

For a MGUS diagnosis, besides other factors, a serum M protein concentration of >30 g/L, fewer than 10 % plasma cells in the bone marrow, no end organ damage, and no evidence of a related plasma cell proliferative disorder must be considered in the clinical context (Group 2003; Kyle and Rajkumar 2007). From a genetic point of view, primary events like an *IgH* translocation or hyperdiploidy are important. They can promote the transformation of a post-germinal center B cell towards increased monoclonal expansion/proliferation. This proliferation ultimately results in a MGUS diagnosis and thus forms the basis for the development of symptomatic MM (Pawlyn and Morgan 2017) (**Figure 3**).

In this development, the evolutionary intermediate stage of SMM was defined. Here, a malignant transformation can lead to the progression from MGUS towards SMM (Salomon-Perzyński et al. 2021). SMM is further defined by a higher clonal burden than MGUS and a variable risk of progression towards MM (Pawlyn and Morgan 2017; Rajkumar et al. 2015). In contrast, the annual risk from a progression from MGUS to symptomatic MM is approximately only 1 % (Kyle et al. 2018). The progression towards MM is characterized by an expansion of plasma cells outside the bone marrow microenvironment for example in the lymph nodes or soft tissue. The MM underlying biology and clinical presentation are addressed in more detail in chapter 1.4. In a final step, an evolution from MM towards plasma cell leukemia is possible; this stage is defined by peripheral blood involvement (Bhutani et al. 2020; Salomon-Perzyński et al. 2021).

The disease's progression and evolution from MGUS towards plasma cell leukemia is driven by secondary events, like secondary genetic events, epigenetic changes, subclonal competition, subclonal cooperation, or the remodeling of the tumor microenvironment (McGranahan and Swanton 2015; Salomon-Perzyński et al. 2021) (**Figure 3**). Taking these factors together, an increased fitness and adaptive potential of random subclone populations under selective pressure can lead to the evolution of the disease (Nowell 1976; Salomon-Perzyński et al. 2021).

**Figure 3. Evolution of plasma cell dyscrasias.** Both primary and secondary genetic events are required for the malignant transformation of a post-GC B cell to MM. New genetic events accumulate in malignant plasmacytes over time affecting the fitness of subclones and leading to the further expansion of some and the extinction of others. Progression from MGUS/SMM to MM is driven by subclonal competition (and likely by its cooperation) and by simultaneous changes in the tumor microenvironment. (1) Branching clonal evolution – the dominant evolutionary pattern in the progression of SMM to MM, with some subclones disappearing (pink, light blue) and others appearing (red, purple, brown) over time; (2) static clonal progression – evolutionary pattern in the progression of SMM to MM, in which the tumor’s subclonal architecture does not change significantly over time. Abbreviations: GC, germinal center; IgH, immunoglobulin heavy chain; MGUS, monoclonal gammopathy of undetermined significance; MM, multiple myeloma; SMM, smoldering multiple myeloma; PCL, plasma cell leukemia. Image adapted and legend retrieved from a publication by Salomon-Perzyński (Salomon-Perzyński et al. 2021), the original article was published under the Creative Commons Attribution 4.0 International License (CC BY 4.0, <https://creativecommons.org/licenses/by/4.0/>).

Of note, the development of light chain amyloidosis (AL) is possible at all dressed stages from MGUS towards plasma cell leukemia. A development from MGUS towards AL was observed in 12 % of the patients with a median disease interval of nine years (Kyle and Rajkumar 2007; Kyle et al. 2004a). Besides the fact that co-occurrence of AL and MM was detected in 10 % of the patients, a progression from AL towards MM is extremely rare (Rajkumar et al. 1998).

### 1.3 Multiple Myeloma

#### 1.3.1 Biology of Multiple Myeloma

As mentioned before, MM is a malignant plasma cell disorder that evolves from the premalignant MGUS and SMM stages. Further, it is defined by an abnormal clonal plasma cell

infiltration in the bone marrow (Greipp et al. 2005; Kyle and Rajkumar 2004; Kyle and Rajkumar 2008). In an epidemiological context, it accounts for approximately 10 % of all hematologic cancers, and the annual age-adjusted incidence in the US is approximately 4.3 per 100000 persons (Kyle and Rajkumar 2008; Kyle et al. 2004b). Additionally, MM is more frequently diagnosed in Black than White persons and slightly more common in males. The overall median age at diagnosis is about 65 years (Firth 2019; Kyle and Rajkumar 2008).

As mentioned in chapter 1.2, translocations, especially of the *IgH* locus, as well as hypodiploidy are described as primary events and occur in almost 100 % of the cases (Walker et al. 2014) (**Table 3**). In this context, hyperdiploid MM is characterized by an overall increased number of 48 – 74 chromosomes, which is based on trisomies of chromosomes 3, 5, 7, 9, 11, 15, 19, and 21 (Chng et al. 2007). However, translocations and hyperdiploidy can be observed for MM as well as MGUS patients and are therefore not sufficient to explain disease progression (Fonseca et al. 2002; Walker et al. 2014).

One possible translocation for the HC locus, t(11;14), is described in the AL chapter 1.4 in more detail. In MM patients, three translocation partners for the HC locus can be frequently observed: a) 20 – 25 % cyclin D1, D3, and possibly D2 (*CCND1*, *CCND2* and *CCND3*); b) 15 % *MMSET* and *FGFR-3*; c) 10 % *c-MAF* and *MAFB* (Chesi et al. 1998; Hanamura et al. 2001; Kuehl and Bergsagel 2002). Besides these primary translocation events, the secondary translocation of *c-MYC* can also frequently be detected in MM patients. This is of special interest due to the fact, that this translocating is associated with an enhanced proliferation (Kuehl and Bergsagel 2002).

Comparable to the results concerning acquired mutations, an increased number of specific genetic aberrations can also be observed during disease progression from MGUS towards MM (López-Corral et al. 2011). MM patients display more often a gain of 1q and a deletion of 13q or 17p as well as a higher amount of the translocations t(11;14) and t(4;14) than MGUS and SMM patients (López-Corral et al. 2011). In general, a gain of 1q, 3q, 9q, 11q, and 15q can be observed in more than 30 % of the MM patients. The most frequent chromosome loss concerns 13q (Kuehl and Bergsagel 2002). However, not only the presence but more specifically the number of affected plasma cells seem to have a prognostic impact and might also influence the disease progression (Avet-Loiseau et al. 2009; López-Corral et al. 2011).

The assumption that additional genetic events are necessary for expansion from MGUS towards the invasive states is further sustained by a higher number of acquired mutations in the context of disease progression (Walker et al. 2014). However, the sides and targeted molecular mechanism did not differ between the different disease stages and are therefore also not fully capable to explain disease progression (Walker et al. 2014).

**Table 3. Primary molecular cytogenetic classification of multiple myeloma.**

IgH = Immunoglobulin heavy chain, MM = multiple myeloma. Retrieved and adapted from (Rajan and Rajkumar 2015). The original article was published under the Creative Commons Attribution 4.0 International License (CC BY 4.0, <https://creativecommons.org/licenses/by/4.0/>).

Subtype	Gene(s) chromosomes affected	Percentage of MM patients
Trisomic – recurrent trisomies involving odd-numbered chromosomes (except for chromosomes 1, 13, and 21)		42
<i>IgH</i> -translocated		30
t(11;14) (q13;q32)	<i>CCND1</i> (cyclin D1)	15
t(4;14) (p16;q32)	<i>FGFR-3</i> and <i>MMSET</i>	6
t(14;16) (q32;q23)	<i>C-MAF</i>	4
t(14;20) (q32;q11)	<i>MAFB</i>	<1
Other <i>IgH</i> translocations	<i>CCND3</i> (cyclin D3) in t(6;14) MM	5
Combined <i>IgH</i> -translocated/trisomic – the presence of trisomies and any one of the recurrent <i>IgH</i> translocations in the same patient		15
Isolated monosomy 14 – few cases may represent 14q32 translocations involving unknown partner chromosomes		4.5
Other cytogenetic abnormalities in the absence of <i>IgH</i> translocations or trisomy or monosomy 14		5.5
Normal/undetected		3

<sup>a</sup> Includes the t(6;14) (p21;q32) translocation and, rarely, other *IgH* translocations involving uncommon partner chromosomes.

Overall, it must be assumed that different genetic events in different pathways lead to the modification of the original non-malignant plasma cell in such a way that the typical MM characteristics are present (Morgan et al. 2012). These characteristics include the already addressed data regarding non-synonymous mutations and copy number abnormalities. In consequence, during the disease progression towards MM, an increase in genetic complexity can be assumed (López-Corral et al. 2011; Walker et al. 2014). This genetic complexity was analyzed using data from more than 800 newly diagnosed MM patients. Here, the natural aging process, defects in the DNA repair mechanism, and mutagenic activity of enzymes, including the activation-induced cytidine deaminase, were identified as important influencing factors for the mutagenesis in MM. (Hoang et al. 2019; Salomon-Perzyński et al. 2021).

Of note, the concept of intra-clonal heterogeneity is also important for MM. In this context, a definition based on different molecular subgroups which are characterized by specific chromosomal aberrations must be given (Manier et al. 2017; Morgan et al. 2012; Rasche et al. 2017). This is necessary since about 80 % of the MM patients display focal lesions (FL). FLs are characterized as an accumulation of malignant plasma cells in restricted regions of the bone marrow (Rasche et al. 2017; Walker et al. 2007). Through a genomic analysis of different FL within the same patients, it was possible to identify spatial heterogeneity. Therefore, the concept of ongoing clonal competition and adaptation to the microenvironment can be assigned to MM (Rasche et al. 2017). This is supported by different findings, such as the observation of site-

specific driver aberrations or a high subclonal percentage of heterogenous mutations. Further, the size of the FL correlated with the number of unshared mutations and chromosomal aberrations (Rasche et al. 2017).

To go more into detail, in the already mentioned multi-region genomic analysis, Rasche et al. analyzed four MM cases with available computer tomography (CT)-guided sample sets. These sample sets were used to analyze the polygenetic relationship of clones from different regions (Rasche et al. 2017). In one of these cases, four samples from FLs at the left chest wall, the lumbar spine 1, the sacrum, and the iliac crest were analyzed. In this analysis, it was possible to identify different genomic profiles and unique driver mutations for each FL (**Figure 4**). Since all analyzed positions share a translocation of *MYC* and an amplification of 1q, a shared ancestor can be assumed. This shared ancestor evolved further in the process of multi-focal progression (Rasche et al. 2017). However, this was not noted for all patients, for example, in another case study a common high-risk ancestor with a distribution in a metastatic fashion was observed (Rasche et al. 2017).

**Figure 4. Multi-regional evolution in a multiple myeloma patient.** Patient with available multiple CT-guided samples was used to analyze the phylogenetic relationship of clones from different regions. The location of samples is marked in the medical images in the right panel using the color code that was assigned to clones (left panel). The letter R indicates the right side of the body. Focal lesions displayed different genomic profiles with each of them containing unique driver mutations. A mutation of the *BRAF* gene affects the serine/threonine-kinase B-Raf, which is known as a proto-oncogene. *KRAS* is a monomeric G-protein and is known to play an important role in the proliferation of tumor cells. A mutation in *STAT3* was associated with spatial heterogeneity in the work of Rasche et al. and is defined as a promising candidate as a novel MM driver (Rasche et al. 2017). HY = hyperdiploid, Amp = amplification, Del = deletion, SNV = single nucleotide variant, LOH = loss of heterozygosity, L1 = lumbar spine 1. Figure and legend retrieved and adapted from (Rasche et al. 2017). ### 1.3.2 Clinical Presentation and Diagnosis of Multiple Myeloma

The International Myeloma Working group defined several criteria for a MM diagnosis. In more detail, in addition to more than 10 % of plasma cells in the bone marrow (**Figure 5, A**) or biopsy-proven plasmacytoma, four other myeloma-defining events (MDE) must be present (Rajkumar 2022; Rajkumar et al. 2014). These MDEs are defined by the established CRAB criteria and include hypercalcemia, renal failure, anemia, or lytic bone lesions (**Figure 5, B**). In more detail: serum calcium  $>0.25$  mmol/L needs to be higher than the upper limit of normal, creatinine clearance  $<40$  mL per minute, hemoglobin value of  $>2$  g/dL below the lower limit of normal and at least one lytic lesion on skeletal radiography, CT, or positron emission tomography-CT (Rajkumar et al. 2014). These criteria were updated and refined in 2022 and established as the current standard SLiM-CRAB criteria for treatment indication of SMM. These SLiM-CRAB criteria are defined by  $\geq 60$  % clonal bone marrow plasma cells, involved serum free light chain ratio  $\geq 100$  mg/L, and more than one FL ( $\geq 5$  mm in size) on magnetic resonance imaging (Rajkumar 2022). It was possible to associate these additional biomarkers each with an approximately 80 % risk of progression to symptomatic end-organ damage (Rajkumar 2022).

The clinical presentation typically includes bone pain and pathological fractures, recurring infections, and abnormal bleeding (Firth 2019). Rare clinical manifestations may include ischemia, heart failure, neurological impairments, and amyloid diseases (Firth 2019).

**Figure 5. Characteristic osteolysis and plasma cell increase in multiple myeloma patients.** (A) Skeleton X-ray of a multiple myeloma patient showing multiple diffuse osteolytic lesions. Figure and legend were adapted and retrieved from (Caldas et al. 2011). The original article was published under the creative common CC BY-NC 4.0 license (<https://creativecommons.org/licenses/by-nc/4.0/>, 20.12.2022) (B) Bone marrow aspirate of a multiple myeloma patient showing numerous plasma cells (WG;  $\times 400$ ). Figure and legend were adapted and retrieved from (Khurana et al. 2016). The original article was published under the Creative Commons Attribution 4.0 International License (CC BY 4.0, <https://creativecommons.org/licenses/by/4.0/>).

In addition to the SLiM-CRAB criteria, the patients should be tested for the presence of a M protein using serum protein electrophoresis and serum immunofixation. Based on these assays, a diagnosis will be established successfully in about 98 % of the MM patients (Chawla et al. 2015; Katzmann et al. 2006; Kyle et al. 2003; Rajkumar 2022). In general, if it is possible to detect more than 5 % of circulating plasma cells in the peripheral blood smear, plasma cell leukemia should be considered (Fernández de Larrea et al. 2021). In addition to the tests necessary for clinical characterization and diagnosis, a fluorescence *in situ* hybridization (FISH) analysis should also be performed for risk stratification. In this context, patients with a deletion of 17p or 1p as well as a t(14;16) or t(14;20) are considered to be at high risk for a lower overall survival (Rajan and Rajkumar 2015).

The estimated prognosis not only considers the CA but also more generally the tumor burden, indicated by staging systems, and the therapy response (Rajkumar 2022; Russell and Rajkumar 2011; Vu et al. 2015). The revised international staging system combines aspects of the tumor burden as well as CA (Palumbo et al. 2015). Stage I is defined by a serum albumin >3.5 gm/dL, a serum beta-2-microglobulin <3.5 mg/L, no high-risk cytogenetics, and a normal serum lactate dehydrogenase level. Stage III applies to patients with a serum beta-2-microglobulin >5.5 mg/L and high-risk cytogenetics like t(4;14), t(14;16), del(17p) or elevated serum lactate dehydrogenase level (Palumbo et al. 2015). Stage II patients are classified as all patients which are not suitable for stage I or III (Palumbo et al. 2015). It was shown that a high level of lactate dehydrogenase can also be associated with lower overall survival (Terpos et al. 2010).

## 1.4 AL Amyloidosis

### 1.4.1 Forms of Amyloidosis

Amyloidosis is characterized as a group of rare diseases, which result from the extracellular deposition of amyloid fibrils. These fibrils are defined by their  $\beta$ -sheet confirmation and can be visualized by a congo-red staining and resulting green birefringence (Jin et al. 2003; Westermark 2005).

Until now, more than 30 proteins have been identified to form fibrils in the human body but it is believed that there are even more proteins with amyloidogenic potential (Sipe et al. 2014; Wechalekar et al. 2016). Based on the underlying precursor protein different forms of amyloidosis can be defined (**Table 4**). Acquired systemic AL and hereditary amyloidosis are associated with the presence of an abnormal protein in the serum. The  $\beta$ 2-microglobulin (A $\beta$ 2m) dialysis-related amyloidosis or reactive systemic amyloidosis are defined by the

excessive occurrence of a normal protein. Wild-type transthyretin (ATTRwt) amyloidosis and atrial natriuretic peptide amyloidosis are forms that are associated with the aging process (Merlini et al. 2018; Wechalekar et al. 2016).

In Western countries, the most frequent form of amyloidosis is systemic AL, next to ATTRwt (Obi et al. 2022; Wechalekar et al. 2016). In general, AL can be defined as an acquired form of amyloidosis (Wechalekar et al. 2016) – only one case study found a hereditary mutation in the CL of a kappa LC (Benson et al. 2015). Besides systemic AL, a localized form is also known. In this case, the LCs deposit at one single anatomic site and form amyloid lesions. However, local AL account only for about 10 % of all amyloidosis cases but no precise population data is available (Basset et al. 2020; Hamidi Asl et al. 1999). In contrast, several studies have been performed to investigate the epidemiology of systemic AL (Merlini et al. 2018). When comparing the results, a range of an annual incidence of 3 to 12.7 per million persons with a median of 10.7 can be calculated (Duhamel et al. 2017; Hemminki et al. 2012; Kyle et al. 1992; Kyle et al. 2004b; Pinney et al. 2013; Quock et al. 2018). Another important epidemiological aspect is that more men than women are affected (Kyle et al. 1992). More precisely, in an analysis of 701 patients, 64 % were male (Kourelis et al. 2017).

**Table 4. Most common forms of systemic amyloidosis.** Reprinted and adapted by permission from Copyright Clearance Center: Springer Nature, Nature Reviews Disease Oligonucleotides, Systemic immunoglobulin light chain amyloidosis, Merlini et al. (2018) (Merlini et al. 2018) (License number 5398791052309). Legend retrieved from (Merlini et al. 2018).

Designation <sup>a</sup>	Parent protein	Systemic and/or localized	Acquired or hereditary	Organs involved
AL	Immunoglobulin light chain <sup>b</sup>	Systemic or localized	Acquired (hereditary <sup>c</sup> )	Heart, kidney, liver, soft tissues, peripheral nervous system (including the autonomic nervous system) and gastrointestinal tract
ATTR	Transthyretin	Systemic	Hereditary	Peripheral nervous system (including the autonomic nervous system), heart, eye, kidney and leptomeninges
		Systemic	Acquired	Heart and ligaments
AA	Serum amyloid A protein	Systemic	Acquired	Predominantly kidney, but may involve liver, gastrointestinal tract and occasionally heart, thyroid and autonomic nervous system
ALECT2	Leukocyte chemotactic factor 2	Systemic	Acquired	Kidney, liver, spleen, adrenals and lungs

Designation <sup>a</sup>	Parent protein	Systemic and/or localized	Acquired or hereditary	Organs involved
AApoAI	Apolipoprotein AI	Systemic	Hereditary	Heart, liver, kidney, peripheral nervous system, testis, larynx and skin
AFib	Fibrinogen $\alpha$ chain	Systemic	Hereditary	Kidney, primarily, with obliterative glomerular involvement
A $\beta_2$ m	$\beta_2$ -microglobulin, wild type	Systemic	Acquired (haemodialysis related)	Musculoskeletal system
	$\beta_2$ -microglobulin	Systemic	Hereditary	Autonomic nervous system

<sup>a</sup>The amyloid fibril protein is designated protein A and is followed by a suffix that is an abbreviated form of the precursor protein name. For example, when amyloid (A) fibrils are derived from immunoglobulin light (L) chains, the amyloid fibril protein is AL. <sup>b</sup>Rare cases of amyloidosis formed by immunoglobulin heavy chains (AH) and by heavy and light chains (AHL) have been reported. <sup>c</sup>One family with a mutation in the constant region of the  $\kappa$  light chain, with cysteine replacing serine at amino acid residue 131, has been reported (Benson et al. 2015).

In general, AL is caused by at least one malignant plasma cell clone which infiltrates the bone marrow. This infiltration is less than 10 % in half of the AL patients. Therefore, the AL clone is relatively small compared to the one in symptomatic MM (Merlini 2017; Milani et al. 2018). But, only the AL clone produces an abnormal number of free LCs which misfold, form prefibrillar aggregates, and finally form fibrils in the extracellular space. These fibrils cause cellular stress and disturb the normal tissue structure and function which can cause lethal consequences (Merlini 2017). In addition to the differences concerning the clone size and the LC behavior, also the kappa/lambda ratio is shifted in AL. For the B cell repertoire of healthy individuals as well as for the M protein of MM patients, more kappa LC (2:1; kappa/lambda) can be detected. In contrast, AL patients display more frequently a lambda LC (1:3; kappa/lambda) (Kyle and Gertz 1995).

#### 1.4.2 Clinical Presentation and Diagnosis of AL Amyloidosis

In most cases, the AL diagnosis is delayed, and drastic organ damage has already taken place. In addition, more than 69 % of the patients display more than one organ involvement at diagnosis (Obici et al. 2005). Unfortunately, it has been reported that survival significantly decreased the more organs were affected (Muchtar et al. 2019). One possible factor for a delayed diagnosis might be that AL-related symptoms are commonly found in elderly people (Milani et al. 2018), which is of importance since the average age at first diagnosis is 65 years (Schönland et al. 2012). Besides the number of affected organs, the patient's age was also linked to a poorer prognosis. A study conducted by the Mayo Clinic showed that patients  $\geq 65$  years had lower survival than younger patients (Muchtar et al. 2019).

Overall, a delayed diagnosis led to higher mortality rates, especially by cardiac involvement or a progression to end-stage renal disease in the first month after diagnosis (Merlini et al. 2018; Muchtar et al. 2017b; Palladini et al. 2014). One study showed that in 40 % of the patients, the diagnosis was confirmed >1 year after symptoms occurred (Lousada et al. 2015). This can especially be observed for MGUS patients – therefore, screening for AL should already be performed at this stage (Al Hamed et al. 2021; Kourelis et al. 2014; Merlini et al. 2018).

Several symptoms can point to a potential AL diagnosis. This includes heart failure with preserved ejection fraction, nephrotic range proteinuria, a mixed axonal demyelinating peripheral neuropathy with autonomic features, or hepatomegaly without imaging abnormalities (Merlini 2017; Merlini et al. 2018; Wechalekar et al. 2016). To secure a diagnosis, it is suggested to perform immunofixation electrophoresis of the serum and urine as well as an immunoglobulin-free LC assay. Further, a tissue biopsy and a histopathological analysis should be conducted (Merlini et al. 2018). However, the underlying biopsy must not be performed on the affected organ. It was shown that a less invasive method like the aspiration of subcutaneous fat or a bone marrow biopsy can lead to a diagnosis in 50 – 80 % of the cases (Merlini et al. 2018; Muchtar et al. 2017a; Quarta et al. 2017). After the detection of amyloid deposits in the biopsies, an accurate typing of the precursor protein is necessary. In this context, a mass spectrometry-based analysis is considered the most successful approach with a reported sensitivity of 88 % and specificity of 96 % (Merlini et al. 2018; Vrana et al. 2014). Besides the already addressed factors, there are also biomarkers available that can detect heart or renal failure with 100 % sensitivity (Merlini et al. 2018). An increased level of the N-terminal provisional brain natriuretic peptide (NT-proBNP) in serum indicates a cardiac involvement (Palladini et al. 2003; Wechalekar et al. 2011), whereas for example, albuminuria can be used for determining renal involvement (Palladini et al. 2014).

AL can affect all organs, except the brain, but in most of the cases, a distinct organ tropism can be observed (Merlini et al. 2018). This includes heart involvement in more than 80 % and a kidney involvement in more than 65 %. Also, the involvement of soft tissue can be observed in over 15 %, followed in descending order by liver involvement, involvement of the peripheral nervous system, and the autonomic nervous system (Merlini et al. 2018). Based on these organ involvements, different symptoms can be noted (**Figure 6**).

**Figure 6. Organ involvement in systemic AL amyloidosis.** The symptoms of monoclonal immunoglobulin light chain (AL) amyloidosis are variable and mimic symptoms observed in common conditions of elderly individuals, such as heart failure (fatigue) and diabetes mellitus (proteinuria and peripheral neuropathy), therefore, contributing to late diagnosis. The presence of heart failure with preserved ejection fraction and thickened ventricular walls with low voltages identified using electrocardiography should raise the suspicion of cardiac amyloidosis. Kidney involvement is characterized by proteinuria and progressive renal failure and manifests as peripheral oedema. The involvement of the gastrointestinal tract results in malabsorption and weight loss that can be prominent in some patients, whereas involvement of the autonomic nervous system can cause invalidating postural hypotension. The presence of prototypic signs such as macroglossia (enlargement of the tongue) and periorbital purpura can immediately lead to the right diagnosis. However, such signs are uncommon and, more importantly, appear late in the course of the disease, frequently appearing when the organ damage caused by amyloid is already irreversible. Reprinted and adapted by permission from Copyright Clearance Center: Springer Nature, Nature Reviews Disease Oligonucleotides, Systemic immunoglobulin light chain amyloidosis, Merlini et al. (2018) (Merlini et al. 2018) (License number 5398791052309). Legend retrieved from (Merlini et al. 2018).

As already addressed, the organ involvement influences the survival of AL patients. Patients with irreversible heart damage, due to a late diagnosis, have a median survival of three to six months (Wechalekar et al. 2013). In contrast, patients without heart failure can survive several years even when not responding to first-line therapy (Merlini et al. 2018). Furthermore, the early diagnosis of patients with renal involvement can prevent the progression towards end-stage kidney disease and dialysis. In contrast, late detection of renal disease is associated with an increased risk of progression (Palladini et al. 2014).

In the context of organ involvement, several staging systems have been established (**Table 5**). The most commonly used cardiac staging system in study design and clinical trials was established by the Mayo Clinic and European investigators (Kumar et al. 2012). It is based on the levels of NT-proBNP, cardiac troponin, and the difference between disease-associated and

uninvolved circulating free light chains (dFLC) (Dispenzieri et al. 2004; Kristen et al. 2010; Palladini et al. 2010; Wechalekar et al. 2013). Additionally, a renal staging system predicting the progression towards dialysis has been established with two biomarkers: eGFR and proteinuria. Applying this system, it was not possible to demonstrate a linkage between the staging and the survival of the patients. However, an impact on kidney survival and quality of life was noted, which also influence the efficiency of the treatment (Kastritis et al. 2017; Merlini et al. 2018; Palladini et al. 2014).

In addition to these staging systems, several other factors can affect patient survival. For example, it was shown that patients with a bone marrow plasma cell infiltration of >10 % have poorer survival rates (Kourelis et al. 2013). Another study found that patients with a dFLC <50 mg/L have a significantly better outcome, independent of the cardiac stage (Dittrich et al. 2017; Milani et al. 2017; Sidana et al. 2018).

**Table 5. Overview of the most commonly used staging systems in AL amyloidosis.** The staging parameters were extracted from the respective publications. (Kumar et al. 2012; Palladini et al. 2014; Wechalekar et al. 2013). dFLC = difference between disease-associated und uninvolved circulation free light chains, cTNT = cardiac troponin T, eGFR = estimated glomerular filtration rate, NT-proBNP = N-terminal provisional brain natriuretic peptide, SBP = systolic blood pressure.

Publication	Alias	Organ	Parameters/staging
Kumar et al. 2012 (J Clin Oncol.)	Mayo	Heart	1 point for each criterion (stage I – IV) <ul style="list-style-type: none"> <li>○ dFLC <math>\geq 18</math> mg/dL</li> <li>○ cTNT <math>\geq 0.025</math> ng/mL</li> <li>○ NT-proBNP <math>\geq 1800</math> pg/mL</li> </ul>
Wechalekar et al. 2013 (Blood)	Euro	Heart	Stratification of advanced cardiac disease with poor prognosis (stage III Mayo) <ul style="list-style-type: none"> <li>○ IIIb: NT-proBNP <math>&gt; 8500</math> ng/L or SBP <math>&lt; 100</math> mm Hg</li> </ul>
Palladini et al. 2014 (Blood)	Renal	Kidney	<ul style="list-style-type: none"> <li>○ I: proteinuria <math>&lt; 5</math> g/d and eGFR <math>&gt; 50</math> mL/min/1.73 m<sup>2</sup></li> <li>○ II: proteinuria <math>&gt; 5</math> g/d or eGFR <math>&lt; 50</math> mL/min/1.73 m<sup>2</sup></li> <li>○ III: proteinuria <math>&gt; 5</math> g/d and eGFR <math>&lt; 50</math> mL/min/1.73 m<sup>2</sup></li> </ul>

Besides these clinical parameters, chromosomal aberrations (CA) also play an important role in the characterization and risk assessment of AL patients. For this purpose, the FISH analysis has been established as routine clinical testing. Based on this analysis, it was demonstrated that AL patients without underlying MM show a CA in 95 % of the cases (Bochtler et al. 2008). Here, the most prominent difference between AL and MM was found concerning t(11;14). This CA was detected in 61 % of the AL patients and only 15 % of MM, MGUS, or SMM patients (Bochtler et al. 2018).

In general, t(11;14) describes the translocation of the HC locus 14q32 with chromosome 11. Moreover, t(11;14) was found to be associated with the lack of intact Ig in the immunofixation in 82 % of the AL cases (Bochtler et al. 2008). Besides the lack of a HC, t(11;14) was also

found to be associated with AL patients with a lower level of plasma cell infiltration (Bochtler et al. 2018). Overall, it was postulated that the lack of a clonal HC binding partner might be part of the pathologic mechanism of AL (Bochtler et al. 2008). Other HC translocations like t(4;14) and t(14;16) were rarely found in AL but, for example, t(4;14) was detected in 26 % of MM patients (AL = 3 %) (Bochtler et al. 2008).

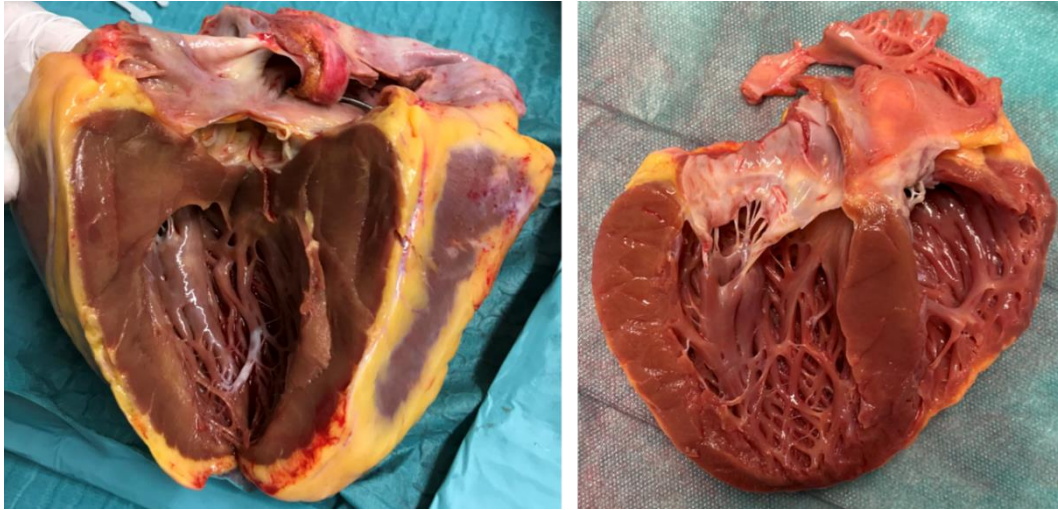

#### 1.4.3 Pathological Effect of Light Chains and Fibrils

The distinct pathological mechanisms in AL which ultimately lead to impaired organ function were and are a major research focus but are not fully understood yet. Further, it is suggested that a difference between soluble proteins and amyloid aggregates must be made. An analysis in AC16 cardiomyocytes showed that LC amyloid fibrils inhibit cell growth and division. This inhibition was not detected for LC soluble proteins but it was noted that they cause cell death dysfunctions and apoptosis (Marin-Argany et al. 2016). Also, a difference between fresh and aged fibrils was found. Aged fibrils displayed an increase in cytotoxicity, which is potentially based on the fact that fibrils fragment into smaller clusters over time. It was stated, that these smaller clusters might be easier to engulf in the cardiomyocytes (Marin-Argany et al. 2016). Another aspect in the context of cytotoxicity is that the cell-cell contact is disturbed through the attachment of fibrils to the plasma membrane, which leads to a decrease in cell viability (Marin-Argany et al. 2016).

Over the years, several groups have established different animal model systems like *Caenorhabditis elegans* (Diomede et al. 2014), zebrafish (Mishra et al. 2013) or mice (Ayala et al. 2021) to investigate the effect of the disease. Researchers have especially tested the effect of cardiogenic LCs due to the devastating effect on patients with heart involvement (Marin-Argany et al. 2016; Merlini 2017). Here, it was noted that in comparison to LC from MM patients, the amyloidogenic LCs displayed a pathological effect. In more detail, the treated worms showed a pharyngeal dysfunction and a reduced life span. This effect was traced back to structural mitochondrial damage (Diomede et al. 2014; Merlini 2017). Similar damage was observed in amyloid-affected hearts from humans (Merlini 2017). It was also shown that amyloid LCs associated with heart involvement induced the p38 mitogen-activated protein kinase signaling (Shi et al. 2010). Since this pathway also mediates the type B natriuretic peptide (BNP) transcription, a linkage between the increased value of BNP/NT-proBNP and the cardiac pathology of the LC can be made (Merlini 2017).

In addition to increased NT-proBNP values, an enlarged septal thickness can also be detected in AL amyloidosis patients with cardiac involvement. This increased stiffness and enlargement

of the heart can be attributed to the amount of deposited fibrils and lead to an overall reduced functionality (**Figure 7**).

**Figure 7. Photos of two heart transplants from AL amyloidosis patients.** The heart transplants were donated for research by two patients treated at the amyloidosis center at the Heidelberg University Hospital. The photos were kindly provided by Prof. Dr. Ute Hegenbart (University Hospital Heidelberg).

#### 1.4.4 Pathway of Fibril Formation

It can be assumed that the amyloidogenic protein exists in two stable forms: the native status and the fibril status which are separated by an energy barrier (Absmeier et al. 2022). Kinetically the process of fibril formation can be divided into three phases (**Figure 8**). The first phase, lag phase, is thermodynamically unfavorable and is characterized by completely or partially disordered monomers that convert into nuclei. After the lag phase, an exponential growth phase can be observed, where the nuclei grow through the addition of monomers into fibrils. This formation and extension of fibrils is then followed by an equilibrium phase, which is also called plateau or saturation phase (Chiti and Dobson 2017).

In this process, the native state needs to unfold and adapt to the energetically more favorable amyloid stage (Hartl and Hayer-Hartl 2009). How this stage transition takes place is not fully understood yet. It is assumed that an additional trigger combined with protein unfolding causes the supersaturation barrier to be disrupted. Through this disruption, the formation of amyloid fibril structures can occur (Absmeier et al. 2022; Adachi et al. 2015).

**Figure 8. Kinetics of fibril formation in vitro.** A specific local concentration of partially folded proteins is necessary for the formation of a critical fibrillar nucleus. The critical concentration for nucleation varies depending on the stability of the light chains. During the lag phase, the conditions do not favour protein aggregation, and fibrils are not formed. However, after the formation of the fibrillar nuclei, protein aggregation into cross- $\beta$ -sheet oligomers occurs, leading to fibril formation and elongation. The concentration of partially folded proteins necessary for fibril elongation is substantially lower than the concentration required for forming the first nuclei. Reprinted and adapted by permission from Copyright Clearance Center: Springer Nature, Nature Reviews Disease Oncoimmunology, Systemic immunoglobulin light chain amyloidosis, Merlini et al. (2018) (Merlini et al. 2018) (License number 5398791052309). Legend retrieved from (Merlini et al. 2018). The original figure was created by V. Bellotti (University of Pavia, Italy) and the usage within this work was also permitted.

Additionally, several factors can influence this transition from LCs to amyloid fibrils, such as the concentration of the precursor protein, the pH, proteolysis, extracellular chaperones, or lipids (Gottwald and Röcken 2021; Merlini 2017). Also, several non-amyloid factors are known to be present in the amyloid deposits, like the serum amyloid P component. This factor binds to amyloid fibrils and may protect them from recognition by the immune system (Gottwald and Röcken 2021; Pepys 2018). Overall, in a study conducted by Kourelis et al., as much as 161 proteins were detected which seem to be amyloid-associated in AL deposits from patients with heart involvement (Kourelis et al. 2020).

Another aspect that needs to be considered in the process of fibril formation is proteolytic activity (Morgan et al. 2017). This is based on the suggestion that amyloidogenic LC dimers are kinetically unstable and that through endoproteolysis amyloidogenic fragments might be generated (Morgan and Kelly 2016). This is of importance as it was shown that only the variable

domains form fibrils, whereas no amyloidogenicity was noted for full-length LCs (Morgan and Kelly 2016). Full-length LCs from patients with amyloidosis unfold more easily than full-length LCs from healthy patients. In consequence, they are assumed to be more prone to proteolytic cleavage (Morgan and Kelly 2016). In this context, several regions seem to be more susceptible to proteolysis than others, which might also be influenced by mutations (Absmeier et al. 2022; Morgan and Kelly 2016).

Kind of the last final step in the process of fibril formation is to bypass the quality control of the endoplasmic reticulum. This control system in the cell monitors proteins to ensure correct folding and assembly and can lead to the degradation of deviant chains. So, only assembled antibodies should be secreted in a healthy individual. (Ellgaard and Helenius 2003; Lee et al. 1999). Nevertheless, also healthy individuals produce LCs in excess of HCs. So, although a small number of free LCs occur among healthy people, it is not clear, how the multitude of LCs in AL patients can bypass this system (Absmeier et al. 2022; Waldmann et al. 1972).

#### 1.4.5 Fibril Structure

Amyloid fibrils can be defined as a linear self-assembly state of polypeptide chains (Chiti and Dobson 2006). Further, they contain spines consisting of many-stranded  $\beta$ -sheets (Eisenberg and Jucker 2012). More precisely, amyloid fibrils are biophysical based on a cross- $\beta$  fiber diffraction pattern (Eisenberg and Jucker 2012).

In 2019, it was possible to resolve the first two cryo-EM structures of an IGLV1-44 (FOR006) (Radamaker et al. 2019) and IGLV6-57 (AL55) AL fibril (Swuec et al. 2019). In the following years, two additional fibril structures of an IGLV3-19 (FOR005) (Radamaker et al. 2021a) and an IGLV1-51 (FOR001) (Radamaker et al. 2021b) AL fibril were resolved (**Figure 9**). These analyses showed that about 77 % of the residues form the ordered part of the fibrils. These ordered parts also contained 79 % of the detected mutations (Radamaker et al. 2021b). However, a central disordered segment was detected in three out of four fibril structures. This led to the assumption that the mutations are not preferentially located in the fibril core (Radamaker et al. 2021b). In addition, the stable fibril cores of these four cases showed a higher aggregation score than the disordered segments (Radamaker et al. 2021b).

Besides structural aspects, the four fibrils share a mutation at the third position of the CDR2 region (Radamaker et al. 2021b). Besides mutations, post-transcriptional modifications were investigated as well. In this context, FOR001 stood out with three post-transcriptional mutations: a disulfide bond, a pyroglutamylation, and a N-glycosylation (Radamaker et al. 2021b). Even though it is not known how glycosylation can attribute to the fibril formation,

they are overrepresented in AL fibrils – especially for kappa LCs (Dispenzieri et al. 2020; Kumar et al. 2019; Radamaker et al. 2021b).

**Figure 9. Location of the mutations in known AL amyloid fibrils and natively folded VL domains.** (A) Location of the mutations in known AL amyloid fibril structures. The fibrils are derived from the GL segments IGLV1-51\*02  $\lambda$ 1 (FOR001, PDB 7NSL) (Radamaker et al. 2021b), IGLV1-44\*01  $\lambda$ 1 (FOR006, PDB 6IC3 10.2210/pdb6IC3/pdb) (Radamaker et al. 2019), IGLV3-19\*01  $\lambda$ 3 (FOR005, PDB 6Z1O 10.2210/pdb6Z1O/pdb) (Radamaker et al. 2021a), and IGLV6-57\*02  $\lambda$ 6 (AL55, PDB 6HUD 10.2210/pdb6HUD/pdb) (Swuec et al. 2019). Disordered parts of the fibril proteins are indicated by dotted lines. Black: CDRs; yellow: Cys; Indigo: mutations in the CDRs and one residue before or after a CDR; magenta: mutations in framework regions; green: residues in the junctional region at the V/J interface. Red star: location of the glycosylation. (B) Sequence alignment of the four fibril proteins. CDRs are marked with gray boxes. Color coding as in (A). (C) Location of mutations in the corresponding, natively folded LC VL domains that are based on the GL segments IGLV1-51\*01 (PDB 5JZ7 10.2210/pdb5JZ7/pdb), IGLV1-44\*01 (PDB 6QB6 10.2210/pdb6QB6/pdb) IGLV3-19\*01 (PDB 6QOE 10.2210/pdb6QOE/pdb) and IGLV6-57\*02 (PDB 7JVA 10.2210/pdb7JVA/pdb) CDRs are marked in black. Color coding as in (a). This image and legend were retrieved from a publication by Radamaker et al. (Radamaker et al. 2021b). The original article was published under the Creative Commons Attribution 4.0 International License (CC BY 4.0, <https://creativecommons.org/licenses/by/4.0/>).

Overall, the analyzed AL fibrils share the typical cross- $\beta$  structure. This structure is stabilized, for example, through backbone hydrogen bonds or interactions between side chains (Absmeier et al. 2022; Radamaker et al. 2021a; Schmidt et al. 2016; Swuec et al. 2019). Besides these aspects, it is noticeable that different morphologies, post-transcriptional modifications, and mutations can be found (Radamaker et al. 2021b).

## 1.5 Aim of the Study

*What are the main questions addressed in this work?*

- Can the difference in the amyloidogenic potential between LCs from AL and MM patients be attributed towards specific sequence characteristics?
- Can the difference in the organ involvement of AL patients be associated with specific sequence characteristics?
- Does the presence of a potential HC binding partner or a high dFLC in the serum of AL patients reflect in specific sequence characteristics of the corresponding LCs?

*What is the underlying relevance of these questions?*

- AL amyloidosis is a rare disease that is often diagnosed at a late stage with potentially lethal consequences for the patients. This condition would be significantly improved, by screening options for MGUS and SMM patients, based on biomarkers. A promising approach provide the disease's underlying LCs themselves. This work focuses on lambda LCs, as AL patients are more likely to display lambda than kappa LCs (3:1). Nevertheless, these AL LCs should be compared with non-amyloidogenic LCs to identify potential crucial characteristics. For this comparison, LCs from the related plasma cell disorder MM, which do not form fibrils, offer the best option. The gained results can then potentially serve as a starting point for a risk stratification model for the disease progression towards AL.
- The specific organ tropism in AL is a characteristic that is not yet fully understood. To further investigate the pathogenic mechanism of the disease, LCs and particularly their mutations offer a promising approach. The underlying hypothesis of this approach is that the composition and mutations of the LCs first influence the misfolding and then the fibril deposition in different organs.
- One hypothesis in AL addresses the influence of a potential HC binding partner. More specific, the presence or absence of a HC might influence the pathological mechanisms of the disease. In this context, there might be a positive selection of certain LCs which exhibit favorable characteristics for one of the two opportunities. Vice versa, when analyzing these LCs, it might be possible to conclude on the pathological mechanisms. The same approach can be applied to a high dFLC. A high dFLC is, besides other aspects, associated with a higher tumor burden and a more aggressive tumor clone. This might also correlate with specific sequence features of the LCs.

## 2 Material and Methods

### 2.1 Material

#### 2.1.1 Equipment and Consumables

The equipment and consumables used in this study are listed in **Table 6** and **Table 7**.

**Table 6. Equipment.**

Name	Manufacturer	Object
µCuvette G1.0	Eppendorf	RNA and DNA concentration measurement
4200 TapeStation system	Agilent	Electrophoresis and concentration measurements
7-2020	NeoLab	Vortex mixer
Accu-jet® pro	Brand	Pipette
B3 professional series microscope	Motic®	Microscope
Biometra® TProfessional thermocycler	Analytik Jena	Thermocycler
BioSpectrometer® basic	Eppendorf	Spectrometer
Centrifuge 5810	Eppendorf	Centrifuge
Centrifuge 5810 R	Eppendorf	Centrifuge
Countess™ II	Thermo Fischer Scientific	Cell counter
Färbekasten nach Hellendahl mit Erweiterung	Roth	Cell fixation
HTMR-133	HLC	Heating thermomixer
Lightning Volt OSP-250L Power Supply	Owl Scientific Inc.	Voltage supply
MC-24 touch microcentrifuge	Benchmark	Centrifuge
MICROMAT 135	AEG	Microwave
Molecular Imager® Gel DOC™ XR+ with image Lab™ Software	Bio RAD	Agarose gel-documentation
multiSUB® MSChoice	Cleaver Scientific	Gel chamber
NextSeq 550 System	Illumina	Next-generation-sequencer
PerfectSpin 24 plus	VWR Peqlab™	Centrifuge
Pipette “Discovery comfort” 100 – 1000 mL, 20 – 200 mL, 2 – 20 mL, 0.5 – 10 mL	HT lab solutions	Pipette
Pipette “Reference” 10 – 100 mL, 0.5 – 10 mL	Eppendorf	Pipette
Pipette “Research” 2 – 200 mL, 0.5 – 10 mL	Eppendorf	Pipette
PLJ 3500-2NM	Kern	Scale
Quantus™ Fluorometer	Promega	DNA quantification
REAX 2000	Heidolph	Vortex mixer
RoboSep™-S	Stemcell™ Technologies	CD138 <sup>+</sup> cell sorting
Schott CLS-1172 100 mL	SCHOTT	Flask
Sprout® Plus	Heathrow Scientific®	Centrifuge
Thermo Scientific™ Cytospin 4 centrifuge	Thermo Fischer Scientific	FISH slide centrifuge

Name	Manufacturer	Object
Thermo Scientific™ PICO™ 17 microcentrifuge	Thermo Fischer Scientific	Centrifuge
Tischabzug Typ 1200	Waldner Scala	Fume hood
Vortex-Genie® 2 – G560E	Scientific Industries	Vortex mixer

**Table 7. Consumables.**

Name	Manufacturer
1.5 mL Eppendorf safe-lock® tubes	Eppendorf
15 mL polystyrene round-bottom tube	Falcon®
2 mL Eppendorf safe-lock® tubes	Eppendorf
5 mL Eppendorf tubes®	Eppendorf
Aqua Spüllösung	B. Braun
Bemis parafilm® M	Heathrow Scientific
C-Chip DHC-N01	NanoEnTek
Corning® Costar® Stripette®, serolog. Pipetten, 5 mL, 10 mL, 25 mL, 50 mL	Merck/Sigma-Aldrich®
Countess™ cell counting chamber slides	Thermo Fischer Scientific/Invitrogen™
Countess™ test beads	Thermo Fischer Scientific/Invitrogen™
DNA LoBind tubes 1.5 mL	neoLab Migge GmbH
Double Cytoslides™ microscope slides	Epredia™
Erlenmeyerkolben 500 mL	NeoLab
EZ double cytofunnel	Epredia™
H <sub>2</sub> O Ampuwa Spüllösung	Fresenius Kabi
KIMTECH science precision wipes	Kimberly Clark Professionals™
PCR SingleCap 8er-SoftStripes 0.2 mL; DNA, DNase, and RNase free	Biozym Scientific
pluriStrainer® 100 µm	PluriSelect
RoboSep™ Filter Tip Racks	Stemcell™ Technologies
SafeSeal tips professional 10 µL, 20 µL, 100 µL, 200 µL, 1250 µL	Biozym Scientific
Semper Care latex powder free	Semperit Technische Produkte
Spitzen SafeSeal SurPhob 10 µL, 20 µL, 200 µL, 300 µL, 1250 µL	Biozym Scientific
Sterile Pasteur Pipette	LP Italiana
Vernichtungsbeutel	NeoLab
Water, DNase, RNase-free	MP Biomedicals. LLC
Zentrifugenröhrchen PP 50 mL	Greiner Bio-One

### 2.1.2 Chemicals and Enzymes

The chemicals and enzymes used in this study are listed in **Table 8**.

**Table 8. Chemicals and enzymes.**

Application	Name	Manufacturer
Bone marrow preparation, cell storage, FISH-slide preparation	Dulbecco's phosphate-buffered solution (DPBS) 10x	Thermo Fischer Scientific/Gibco™
Bone marrow preparation	EDTA – solution pH 8.0 (0.5 M) for molecular biology	PanReac AppliChem
	Fetal bovine serum (FBS), qualified, HI	Thermo Fischer Scientific/Gibco™

Application	Name	Manufacturer
	Histopaque® 1077	Merck/Sigma-Aldrich®
	UltraPure™ 0.5 M ethylenediaminetetraacetic acid (EDTA), pH 8.0	Thermo Fischer Scientific
	Ammonium chloride solution (NH <sub>4</sub> Cl)	Stemcell™ Technologies
Cell counting	Trypan blue stain 0.4 %	Thermo Fischer Scientific/Gibco™
	Tuerk's solution	Merck
Cell storage	Buffer RLT	Qiagen
	2-Mercaptoethanol	Thermo Fischer Scientific/Gibco™
CD138 <sup>+</sup> cell sorting	RoboSep™ buffer (Ready-to-use)	Stemcell™ Technologies
DNA/RNA Isolation	Ethanol absolute ≥99.8 %	VWR Chemicals
FISH-slide preparation	Acetic acid 100 %	Thermo Fischer Scientific/Carl Roth™
	Methanol 99.9 %, p.a.	Thermo Fischer Scientific/Carl Roth™
Gel electrophoresis	Take5™ 6x loading dye solution	highQu
	Agarose basic for biochemistry	neoFroxx
	SYBR® safe DNA gel stain	Thermo Fischer Scientific/Invitrogen™
	Tris acetate-EDTA (TAE) buffer 10x	Merck/Sigma-Aldrich
	Take5™ 50 bp DNA ladder	highQu
NGS	D1000 reagents	Agilent
	D1000 ScreenTape	Agilent
	NaOH 10 M BioUltra	Merck/Sigma-Aldrich
	Nuclease free water	Ambion®
	Tris-hydrochloride, 1 M-solution (pH 7.0/Mol. Biol.)	Thermo Fischer Scientific
PCR component	AmpliTaq Gold™ DNA polymerase with buffer II and MgCl <sub>2</sub>	Thermo Fischer Scientific/Applied Biosystems™
	dNTP Set 100 mM solutions	Thermo Fischer Scientific
Reverse transcriptase reaction	Oligo(dT)18 oligonucleotide, 0.5 µg/µL	Thermo Fischer Scientific

### 2.1.3 Buffer

The buffers used in this study are listed in **Table 9**.

**Table 9. Buffer.** PBS = phosphate buffered saline, DPBS = dulbecco's phosphate-buffered saline, FBS = fetal bovine serum, EDTA = ethylenediaminetetraacetic acid, TAE = Tris acetate-EDTA.

Buffer	Composition/Manufacturer	Application
GTC buffer	25 mL RLT buffer 250 µL 2-mercaptoethanol	Cell storage

Buffer	Composition/Manufacturer	Application
Methanol – glacial acetic acid	60 mL methanol 20 mL acetic acid	Cell fixation
NH <sub>4</sub> Cl – lysis	500 mL ammonium chloride solution 100 mL H <sub>2</sub> O distilled	Erythrocyte cell lysis
PBS-buffer	900 mL H <sub>2</sub> O distilled 100 mL 10x DPBS	Cytospin, cell storage “dry pellets”
PBS-EDTA-FCS	900 mL H <sub>2</sub> O distilled 100 mL 10x DPBS 1 mL FBS 4 mL EDTA 0.5 M	Bone marrow preparation
TAE-buffer 1x	500 mL TAE 10x 4500 mL H <sub>2</sub> O	Gel electrophoresis

## 2.1.4 Oligonucleotides

The oligonucleotides used in this study are listed in **Table 10**.

**Table 10. Oligonucleotides.** The oligonucleotides were produced and the T<sub>m</sub>-calculation was performed by Eurofins. Devel. = developer, SH = Dr. sc. hum. Stefanie Huhn, NB = Natalie Berghaus, NA = not available.

Name	Devel.	Sequence [5'-3']	Purpose (alias)	T <sub>m</sub> [C°]
VLKL12a_Huhn <sup>a</sup>	SH	GGTCCTGGGCTCA GTCTG	Amplification of IGLV1 and IGLV2, (1_Huhn_fw)	60.5
VLKL3c_Huhn <sup>a</sup>	SH	TGGTACCAGCAGA AGCCAGG	Amplification of IGLV3, (2_Huhn_fw)	61.4
VLKL4a_Huhn <sup>a</sup>	SH	CCAGCCTGTGCTG ACTCA	Amplification of IGLV4, (3_Huhn_fw)	58.2
VLKL7a_Huhn <sup>a</sup>	SH	CAGACTGTGGTGA CTCAGGAG	Amplification of IGLV7, (4_Huhn_fw)	61.8
JLHD123_rv <sup>a</sup>	SH	CTAGGACGGTGAG CTTGGTCCC	Amplification of IGLJ1, IGLJ2 and IGLJ3, (5_Huhn_rv)	65.8
JLKL4_rv <sup>a</sup>	SH	GACTCATCTAAAA TGATCAGCTGGG	Amplification of IGLJ4, (6_Huhn_rv)	61.3
JLKL5_rv <sup>a</sup>	SH	AGACTCATCTAGG ACGGTCAG	Amplification of IGLJ5, (7_Huhn_rv)	59.8
β2-MRG_3	NA	TGTCGGATTGATG AAACCCAG	Establishment and verification of the full-length λ light chain sequencing method	57.9
β2-MRG_5	NA	CTCGCGTACTCT CTCTTTCT	Establishment and verification of the full-length λ light chain sequencing method	59.8
CLKL_A_rv_NB	NB	CACTGTCTTCTCC ACGGTG	Amplification of IGLC, (13_NB_rv)	58.8
CLKL_B_rv_NB	NB	CCCTTCATGCGTG ACCTG	Amplification of IGLC, (14_NB_rv), discarded in favor of CLKL_A_rv_NB	58.2
VLKL3_A_fw_NB	NB	CCTATGAGCTGAC ACAGCC	Amplification of IGLV3, N-terminal elongated, (15_NB_rv)	58.2
VLKL6_A_fw_NB	NB	CAGCCCCACTCTG TGTCG	Amplification of IGV6-57, (22_NB_rv)	60.5

Name	Devel.	Sequence [5'-3']	Purpose (alias)	Tm [C°]
VLKL3_H_fw_NB	NB	GCTGACTCAGGAC CCTGC	Amplification of IGLV3-19, N-terminal elongated, (29_NB_rv)	60.5
VLKL3_I_fw_NB	NB	CCCTCAGTGTCCG TGTCC	Amplification of IGLV3-1, N-terminal elongated, (36_NB_rv)	65.0
VLKL3_B_fw_NB	NB	GCCAGGATTACCT GTGGG	Amplification of IGLV3-21, N-terminal elongated, discarded, (23_NB_fw)	58.2
VLKL3_E_fw_NB	NB	GTGTCAGTGGCCC CAGG	Amplification of IGLV3-21, N-terminal elongated, discarded, (26_NB_fw)	60.0
VLKL3_G_fw_NB	NB	GGAAGTAAAAGTG TGCCTGG	Amplification of IGLV3-21, N-terminal elongated, discarded, (28_NB_fw)	57.9
MM142_fw	NB	CCTATGAGGTGAC TCAGCC	Sequence verification of MM142	64.7
MM120_fw	NB	CCTTTGCGCTGAC TCAGC	Sequence verification of MM120	65.5

<sup>a</sup>(Huhn 2018)

### 2.1.5 Kits and Standards

The kits and standards used in this study are listed in **Table 11**.

**Table 11. Kits and standards.**

Name	Protocol	Manufacturer
AllPrep DNA/RNA/Protein Mini Kit and QIAshredder Kit	"Simultaneous purification of genomic DNA, total RNA and total protein from animal and human Cells"	Qiagen
EasySep™ Human CD138 Positive Selection Kit II	"Human CD138 WB and BM positive selection II 17887"	Stemcell™ Technologies
High Pure PCR-Product Purification Kit	"Purification of PCR products in solution after amplification"	Roche
High-Capacity cDNA Reverse Transcription Kit with RNase Inhibitor	"High capacity cDNA reverse transcriptase kit"	Thermo Fischer Scientific/Applied Biosystems™

### 2.1.6 Next-Generation Sequencing

The next-generation sequencing kits used in this study are listed in **Table 12**.

**Table 12. Next-generation sequencing reagents and kits.**

Name	Manufacturer
IDT® for Illumina® DNA/RNA UD Indexes Set B, tagmentation (96 Indexes)	Illumina
Illumina® DNA Prep, (M) tagmentation (24 samples)	Illumina
NextSeq 500/550 Mid Output Kit v2.5 (150 cycles)	Illumina
NextSeq PhiX Control Kit	Illumina
QuantiFluor® ONE dsDNA System	PROMEGA

## 2.1.7 Counterprograms and Websites

The computer programs and websites used in this study are listed in **Table 13**.

**Table 13. Computer programs and Websites.**

Name	Application

## 2.2 AL Amyloidosis Patients and Samples

Samples and data from AL patients which displayed a disease associated lambda LC and had visited the Amyloidosis Centre of the University Hospital Heidelberg between January 2019 and November 2021 were included in this work. The study was approved by the Ethics Committee of the University of Heidelberg (S-123/2006, renewed 07.12.2021) and followed the Helsinki guidelines for research of human subjects. All patients provided written informed consent allowing research on their sample material and clinical data. All patients received therapy according to local standards – additionally, eight patients included in this analysis received a heart transplant (FOR117, FOR130, FOR140, FOR161, FOR196, FOR197, FOR214, and FOR218).

Patients underwent bone marrow aspiration as part of clinical diagnostics workups. The aspirates were forwarded to the GMMG central laboratory and biobank multiple myeloma which is under the lead of Dr. sc. hum. Stefanie Huhn (University Hospital Heidelberg). Patients who underwent bone marrow aspiration before the start of this work (n = 22) and had leftover sample material available in the biobank were also included in this study. Fresh bone marrow aspirate samples were processed according to the following protocols in chapter 2.5. In the framework of this study, biobank-derived samples were processed and analyzed as described starting from chapter 2.6.

### 2.3 Multiple Myeloma Patients and Samples

This study included samples and data from 52 newly diagnosed MM patients which displayed a dominant lambda LC and were treated in GMMG-HD6 clinical trial (EudraCT No.: 2014-003079-40) (Salwender et al. 2019). The trial was performed in accordance with the declaration of Helsinki and the European Clinical Trial Directive (2005) and was approved by the local ethics committees of all participating institutions. All patients provided written informed consent before participating in the study and allowed research on their sample material and clinical data. The GMMG study group provided samples as well as clinical data and the board of GMMG e.V. approved the usage within this work.

Bone marrow sample preparation was not performed within the framework of this work but followed the protocols applied for AL samples (chapters 3.2 – 3.3.2). In addition, LC sequences were generated using a bulk ribonucleic acid (RNA) sequencing approach (chapters 2.7.2 and 2.8.2) which was not performed as part of this work.

In this work, several MM samples were used for sequence validation. In these cases, the GMMG study group provided RNA which was processed and analyzed following the protocols in chapters 2.6.3 – 2.9.

### 2.4 Clinical Characteristics of the Cohorts

Clinical parameters of the AL patients were collected and analyzed on basis of the clinical patient reports. The definition of organ involvement was performed based on established criteria (Gertz et al. 2005) by Prof. Dr. med Ute Hegenbart (University Hospital Heidelberg) and patients were indicated having “dominant heart involvement” or “dominant heart and kidney involvement” if no other clinically relevant organ manifestation was noted. AL patients with dominant kidney involvement and all patients who could not be classified into one of these three groups were analyzed by Sarah Schreiner (University Hospital Heidelberg).

The clinical parameters of the MM patients were retrieved from the dataset provided by the GMMG study group. The patients enrolled in the GMMG-HD6 trial, must be newly diagnosed with MM, must not be treated beforehand and a systemic AL amyloidosis was excluded. The more detailed inclusion and exclusion criteria for this study have been published by Salwender et al. and are listed in the **Supplementary Information Table 1** (Salwender et al. 2019).

Within the framework of this work, several clinical characteristics were evaluated. The responsible investigator or institution, the starting material, the applied test, and the reference areas are listed in **Table 14**.

**Table 14. Overview of the clinical characteristics evaluated in this study, who collected them, the reference areas, and the analysis methods used.**

No information was available for the MM cohort for the following parameters: bone marrow aspirate volume, percentage of CD138<sup>+</sup> plasma cells in the sample, number of cell sorts with no harvested CD138<sup>+</sup> plasma cells, GFR CKD-EPI, NT-proBNP, TNT. The bone marrow aspirates of all AL amyloidosis patients, regardless of the organ involvement and a kappa or lambda light chain, performed in the course of clinical diagnostics were processed in equal parts by Sarah Schreiner and myself. In this context, the volume of samples was recorded. The highest measured percentage of a genetic aberration in the FISH result was defined as the proportion of the main clone (Bochtler et al. 2018). Inv. = Investigator, ALZ = Zentrallabor-Analysezentrum University Hospital Heidelberg, NT-proBNP = N-terminal provisional brain natriuretic peptide, PC = plasma cells, LC = light chain, FISH = fluorescence *in situ* hybridization, HC = heavy chain, GFR CKD-EPI = calculation of the glomerular filtration rate using the formula established by the Chronic Kidney Disease Epidemiology Collaboration, AP = alkaline phosphatase, hsTNT = heart associated troponin T. IFE = IFE = immunofixation electrophoresis in serum, MCL = Molekular-cytogenetisches labor University Hospital Heidelberg, CLIA = chemiluminescence-immunoassay, ECLIA = electrochemiluminescence-immunoassay, BM = bone marrow, NB = Natalie Berghaus, SS = Sarah Schreiner, PIC = physician in charge.

Clinical characteristics	Inv.	Starting material and test	Normal range
BM aspirate volume [mL]	NB, SS	Measurement	-

## 2.5 Bone Marrow Sample Preparation

### 2.5.1 Isolation of Mononuclear Cells

To isolate the mononuclear cells, the bone marrow samples were processed following an internal revised quality management document and a standard operating procedure document (SOP) ("SOP für Dichtegradienten-Zentrifugation von PB und KM", step: "Ficoll vor Sort",

last saved 15.08.2022, revised by Stefanie Huhn) (**Supplementary Information Figure 2**). In this context, a density gradient centrifugation followed by an erythrocytes cell lysis was performed.

### 2.5.2 CD138-Cell Sorting

The CD138<sup>+</sup> positive selection was performed as part of the clinical routine diagnostic and led to samples with a high purity of tumor cells. CD138 is an antigen, which is highly expressed on malignant plasma cells in peripheral blood and bone marrow of patients with monoclonal gammopathies – including AL and MM (Chilosi et al. 1999; Kriegsmann et al. 2018; Ridley et al. 1993; Wijdenes et al. 1996). Therefore, analysis and sequencing of cDNA obtained from CD138<sup>+</sup> sorted cells should significantly reduce background signals and allow LC analysis of the malignant plasma cells with fewer disturbance of germline signals.

The isolation of CD138<sup>+</sup> cells was performed according to an internal revised quality management document and SOP ("SOP zur Roboterunterstützten CD138<sup>+</sup> Sortierung von Probenmaterial nach dem StemCell Protokoll", last saved 15.08.2022, revised by Stefanie Huhn) (**Supplementary Information Figure 3**). The isolated mononuclear cells were used for a robotry (RoboSep<sup>TM</sup>-S – The Fully Automated Cell Separator; Stemcell<sup>TM</sup> Technologies) supported magnetic-bead-based CD-138<sup>+</sup> cell sorting (EasySep<sup>TM</sup>; Stemcell<sup>TM</sup> Technologies). For this purpose, the manufacturer provided buffers, magnetic beads, and antibodies. For cell sorting, the protocol "Human CD138 WB and BM positive Selection II 17887" was used.

The cell counts before as well as after cell sorting for the CD138<sup>-</sup> fraction were determined with 10 µL of the sample and 90 µL of Trypan blue using a cell counter (Countess<sup>TM</sup> II; Thermo Fischer Scientific). This was performed following an internal revised quality management document and SOP ("SOP zum Zählen der Zellzahl von Proben mittels Countess", last saved 15.08.2022, revised by Stefanie Huhn) (**Supplementary Information Figure 4**). The cell count of the positive fraction was always determined according to the CD138<sup>+</sup> cell sorting protocol using a microscope (10µl Trypan Blue Stain 0.4 % + 10µl cell suspension; C-Chip Neubauer Improved DHC-N01) (**Supplementary Information Figure 5**) (B3 professional series microscope; Motic®).

The purity of the CD138<sup>+</sup> samples were not determined due to the rarity of CD138<sup>+</sup> cells and their value for research. Nevertheless, FISH analyses based on the CD138<sup>+</sup> samples suggest a median purity of 95 %.

### 2.5.3 Cytospins

To gain information about the genetic aberrations of the patients it is necessary to generate cytopsin slides for the FISH analysis. The FISH analysis is a clinical standard diagnostic workup and was carried out in the molecular-cytogenetic laboratory of the University Hospital Heidelberg under the leadership of Prof. Dr. sc. hum. Anna Jauch. The slides were prepared following an internal revised quality management document and SOP ("SOP zur Erstellung von Präparaten für die Zytogenetische Analyse von Myelomzellen", last saved 15.08.2022, revised by Stefanie Huhn) (**Supplementary Information Figure 5**). Data was – in return – available via the clinical patient reports.

### 2.5.4 Cell-Pellets

The CD138<sup>+</sup> sorted cells were divided up and stored according to an internal revised quality management document and SOP ("Amyloidose – SOP Produkte und Materialaufteilung", approved: 07.12.20, approved by Stefanie Huhn) (**Supplementary Information Figure 6**). Providing slides for the FISH analysis (3.2.3) has the highest priority; as second priority GTC pellets and as third priority "dry-pellets" should be provided. This accounts for the CD138<sup>+</sup> fraction as well. Within the framework of this work, GTC pellets were used for DNA and RNA extraction. GTC, or more precisely guanidinium thiocyanate, and  $\beta$ -mercaptoethanol are in this workup commonly used as nucleic acid protectors.

## 2.6 Molecular Biological Methods

### 2.6.1 Isolation of Genomic DNA and RNA

The isolation of genomic DNA and RNA was performed using the kit "AllPrep DNA/RNA/Protein Mini Kit" (Quiagen), following the protocol "Simultaneous Purification of Genomic DNA, Total RNA and Total Protein from Animal and Human Cells". No additional RLT buffer with  $\beta$ -mercaptoethanol was added, due to sample storage in GTC buffer. The lysate was directly used for homogenization using a QIAshredder. For elution of total RNA, 15  $\mu$ L elution buffer was added and the samples were centrifuged for 1 min at 13000g. This was repeated a second time, to obtain a final volume of 30  $\mu$ L. A second centrifugation step was also performed for the DNA elution (2x 50  $\mu$ L) – no protein was extracted. In the framework of this study, only the extracted RNA was used for further experiments.

### 2.6.2 DNA and RNA Concentration Measurement

The total DNA and RNA concentration was determined using a spectrometer (BioSpectrometer® basic; Eppendorf) and 2 µL of the sample. For DNA measurement 2 µL elution buffer and for RNA measurement 2 µL water were used as a blank.

### 2.6.3 Reverse Transcriptase Reaction

The reverse transcriptase reaction was performed using the "High capacity cDNA reverse transcriptase Kit" (Thermo Fischer Scientific/Applied Biosystems™) kit following the manufacturer protocol.

### 2.6.4 Polymerase-Chain Reaction

The polymerase-chain-reaction (PCR) for lambda LC amplification was performed following a published protocol (Huhn 2018) (AmpliTaq Gold™ DNA polymerase with buffer II and MgCl<sub>2</sub>; Thermo Fischer Scientific/Applied Biosystems™ and dNTP Set 100 mM solutions; Thermo Fischer Scientific). In addition, several oligonucleotides for full-length lambda LC sequencing were adapted from this protocol (**Table 10**). In a first PCR, a multiplex oligonucleotide set consisting of already developed forward oligonucleotides (VLKL12a\_Huhn, VLKL3c\_Huhn, VLKL4a\_Huhn, VLKL7a\_Huhn) was used. These oligonucleotides have been shown to bind on the common IGLV families. For sequencing of the full-length lambda LCs, a reverse oligonucleotide located in the IGLC segment was newly established (CLKL\_A\_rv\_NB). This first PCR procedure was developed using provided RNA (by Dr. sc. hum Mohammed H.S. Awwad, University Hospital Heidelberg) from two cell lines (OPM2, RPM1). The RNA was processed following the protocol in chapter 2.6.3. It was shown, that the oligonucleotide combination successfully amplified the complete lambda LC and that the subsequent Sanger sequencing was of good quality (**Supplementary Information Figure 1**). Initially, FOR101 and FOR102 were sequenced with four different oligonucleotide combinations and it was possible to detect the same underlying sequence in all sequencing reactions. The forward oligonucleotides were in all cases a multiplex consisting of VLKL12a\_Huhn, VLKL3c\_Huhn, VLKL4a\_Huhn, VLKL7a\_Huhn as reverse oligonucleotide a) JLHD123\_rva and JLKL4\_rva b) CLKL\_A\_rv\_NB and CLKL\_B\_rv\_NB c) CLKL\_A\_rv\_NB or d) CLKL\_B\_rv\_NB were used. Thus, the protocol (VLKL12a\_Huhn, VLKL3c\_Huhn, VLKL4a\_Huhn, VLKL7a\_Huhn, and CLKL\_A\_rv\_NB) was applied to the remaining patient samples. In this process, depending on the sequence quality and the detected IGLV family, additional PCR steps with newly established oligonucleotides were performed (**Figure 10**). When a sequence displayed multiple nucleotide signal overlaps, a PCR with VLKL6\_A\_fw\_NB was performed to confirm or exclude association with the IGLV6-57

family. For LC sequences with poor quality, a single plex PCR using only the respective forward oligonucleotide was performed. Due to the fact, that the VLKL3c\_Huhn oligonucleotide is located in the FR2 of the IGLV3 reference sequences an additional PCR (VLKL3\_A\_fw\_NB) was performed to cover the complete IGLV3-segment. In addition, for sequencing of the IGLV3-19 (VLKL3\_H\_fw\_NB) as well as IGLV3-1 (VLKL3\_I\_fw\_NB) family an additional PCR was performed. For sequencing full-length IGLV3-21 LCs, it was possible to generate two N-terminal resolved sequences using the VLKL3\_A\_fw\_NB oligonucleotide. Three additional oligonucleotides (VLKL3\_B\_fw\_NB, VLKL3\_E\_fw\_NB, VLKL3\_G\_fw\_NB) were tested using three samples (FOR154, FOR162, and FOR169) but it was not possible to generate an evaluable N-terminal elongated sequence using the same oligonucleotide in all three cases.

**Figure 10. Polymerase chain reaction scheme for sequencing full-length lambda light chains with associated oligonucleotides.** Multiplex forward oligonucleotide set: VLKL12a\_Huhn, VLKL3c\_Huhn, VLKL4a\_Huhn, VLKL7a\_Huhn.

If it was possible to generate different sequences with the same sequence quality for one sample – indicated by the number of not unambiguously determined AA positions based on nucleotide signal overlaps – these samples were classified as not evaluable.

The verification of the MM sequences was performed using a single-plex PCR with the respective forward oligonucleotide and CLKL\_A\_rv\_NB. For the IGLV3-1 assigned MM sequences MM142 (MM142\_fw) and MM120 (MM120\_fw) a patient-specific oligonucleotide was used.

### 2.6.5 Analytic Gel-Electrophoresis

The analytic gel-electrophoresis was performed in horizontal chambers (multiSUB® MSChoice; Cleaver Scientific) filled with TAE-buffer (120V, 15 min). For agarose gels 1.5 % agarose and 1 % Syber Safe (SYBR® Safe DNA gel stain; Thermo Fischer Scientific/Invitrogen™) solved in TAE-buffer was used. For analysis, 5 µL of the sample and 1 µL loading dye (Take5™ 6x loading dye solution; highQu) were mixed and 3 µL gen ruler (Take5™ 50 bp DNA Ladder) were used as reference. The visualization was performed using a gel documentation system with corresponding software (Molecular Imager® Gel DOC™ XR+ with Image Lab™ Software; Bio RAD).

### 2.6.6 PCR-Product Purification

For purification of the PCR-products the "High Pure PCR-Product Purification Kit" (Roche) following the protocol "Purification of PCR-Products in Solution after Amplification" was used. The elution step was performed with each 15 µL and two centrifugation steps (13000g for 1 min) instead of 50 – 100 µL and a one-minute centrifugation step (13000g).

## 2.7 DNA Sanger Sequencing

For complementary DNA (cDNA) Sanger sequencing, samples were adjusted to a final concentration according to the manufacturer's instructions. Together with the corresponding oligonucleotides (10 pmol/µL), the samples were sent to Eurofins/GATC (SupremeRun Tube) for sequencing.

## 2.8 Next-Generation Sequencing

### 2.8.1 AL Amyloidosis Patients

To further characterize the sequence composition of IGLV3-21 samples a next-generation sequencing (NGS) analysis was performed for seven patients/samples. The Illumina DNA Prep protocol and a Next Seq 550 (Illumina) were used for this purpose. These experiments were

carried out together with Sarah Schreiner (University Hospital Heidelberg) and Dr. rer. nat. Philipp Reichert (University Hospital Heidelberg).

Two different approaches were chosen per patient/sample. In the first approach, PCR samples generated via a multiplex forward oligonucleotide set (VLKL12a\_Huhn, VLKL3c\_Huhn, VLKL4a\_Huhn, VLKL7a\_Huhn) and the reverse oligonucleotide (JLHD123\_rv) were analyzed (MP\_NGS\_PCR). The multiplex oligonucleotide set was shown to successfully amplify the commonly used IGLV segments. The second approach concerns PCR samples that were generated using the oligonucleotides VLKL3\_A\_fw\_NB and JLHD123\_rv (N\_NGS\_PCR). The PCRs followed the protocol in chapter 2.6.4.

For each approach, two PCRs were performed and pooled before tagmentation. For sample processing, the Illumina document # 1000000025416 v09 (June 2020) "Illumina DNA Prep Reference Guide" was used as a guideline as well as the corresponding kits (**Table 12**).

The working steps and aberrations are listed below:

- Tagmentation of Genomic DNA
  - 500 ng per sample was used
- Post Tagmentation Cleanup
- Amplify Tagmented DNA
- Clean Up Libraries
- Pool Libraries
- Check Library Quality

The samples were checked for quality using both the Quantus (Quantus™ Fluorometer; Promega) and the Tapestation (4200 TapeStation System; Agilent) systems.

The quality check using the Tapestation system was performed following an internal revised quality management document and SOP ("SOP zur Automatischen Elektrophorese am TapeStation System", step: "DNA, PCR Produkte, NGS Library", approved 08.06.2021 by Stefanie Huhn). In addition, the Quantus™ fluorometer and the corresponding QuantiFluor® ONE dsDNA System were used for quality check and concentration measurements following the manufacturer protocol ("QuantiFluor ONE dsDNA System Quick Protocol FB200").

- Dilute Libraries to the Starting Concentration

In a first step, the molarity of the individual libraries was calculated using the following formula:

$$X \text{ nM} = 10^6 \times \frac{\text{library concentration (ng/}\mu\text{L)}}{660 \text{ g/mol} \times \text{average library size in bp}}$$

In the next step, the individual libraries were diluted to achieve a concentration of 2 nM in 15  $\mu\text{L}$  RBS buffer. This was possible for all samples except FOR169 in the N<sub>NGS\_PCR</sub> approach. So, only 15.0  $\mu\text{L}$  instead of 16.7  $\mu\text{L}$  of the sample was used. Subsequently, 5  $\mu\text{L}$  of each library was pooled.

The Illumina protocol "NextSeq System Denature and Dilute Libraries Guide" (Document # 15048776 v09 December 2018) was used to dilute the libraries and pHIX to the start concentration of 1.4 pM.

The run was started according to the guidelines of the "NextSeq 500 System Guide" (Document # 15069765v06 June 2019) document. In addition, the "Local Run Manager Generate FASTQ Analysis Module Workflow Guide" (Document # 1000000003344 July 2018) was used.

### 2.8.2 Multiple Myeloma Patients

The bulk RNA NGS sequencing of MM samples was not performed within the framework of this work. Sequencing libraries were prepared using the Illumina TruSeq stranded mRNA kit. Sequencing was performed on the Illumina NovaSeq 6000 PE 100 S1 platform.

## 2.9 Analysis

### 2.9.1 Sanger Sequencing Analysis

For analysis of the Sanger sequencing results the ab1 files (provided by Eurofins) of the forward and reverse sequencing reaction were analyzed using MEGA (Tamura et al. 2021). To ensure a high sequence quality the sequences were trimmed at the N- und C-terminus and each position was analyzed concerning nucleotide overlaps. If present, the IUPAC-IUB code was used to specify these positions. Afterwards, the forward and reverse sequences were combined into one full-length LC sequence. In the next step, the ExPASy Translate tool (Duvaud et al. 2021) was used for translation into an AA sequence. Each nucleotide triplet containing an uncertain position was analyzed and if possible, the respective AA was complemented.

### 2.9.2 Next-Generation Sequencing Analysis

The bioinformatic analysis of the AL and MM NGS experiments was not performed within the framework of this work.

The bioinformatical data processing concerning the AL IGLV3-21 samples, was performed by Sarah Schreiner (University Hospital Heidelberg) using MIXCR (Bolotin et al. 2015) and the

following commands: `Java -jar mixcr.jar analyze shotgun --verbose -- species hs -- starting-material dna -- receptor-type bcr --contig-assembly sum.fastq analysis.`

The bioinformatical data processing concerning the MM samples, was performed by Dr. re. nat. Alexandra M. Poos (University Hospital Heidelberg) also using MIXCR to extract the full sequences of the IG lambda receptor (option: `--contig-assembly`) (Bolotin et al. 2015)

Within the framework of this work, the cDNA sequences were translated using the ExPASy "Translate" tool (Duvaud et al. 2021). In the following, the AL and MM sequences, regardless of Sanger sequencing or NGS, were analyzed equally.

### 2.9.3 IGL Family Assignment

The IGLV family assignment was performed using the cDNA sequence and VBase2 (Retter et al. 2005) as well as the AA sequence and Ensembl Blast (Howe et al. 2021). If a deviation between the two analysis platforms was indicated, the sequence was stated as non-evaluable. The IGLJ segment was identified using the cDNA sequence and VBase2 and the IGLC segment using the AA sequence and Ensembl Blast. The CDR regions were determined using abYsis (Swindells et al. 2017).

### 2.9.4 Mutation Analysis

For sequence analysis, the VBase2 IGLV reference sequence was used as standard. However, in some cases, a deviation between the IGLV reference deposited in Vbase2 and Ensembl can be noted and a mutation was only indicated if a deviation of the patient-derived LC towards both reference sequences was noted. This did not concern the IGLV-IGLJ-linker region and in this context, the VBase2 reference was again used as standard. For the IGLJ segment, the reference sequences deposited in GenBank (Benson et al. 2013) were used. IGLJ2\*01 and IGLJ3\*01 (Gene ID: 28832) show the same cDNA and AA sequence and are therefore defined as IGLJ2. IGLJ3\*02 (Gene ID: 28831) is defined as IGLJ3. For the IGLC segment, the Ensembl reference sequences were used but due to the fact, that the AA sequences contain an undefined AA at the first position, the corresponding GenBank reference sequences were considered at this position. Sequence alignments were performed using Clustal omega (Madeira et al. 2019). For the calculation of the median mutation count and frequency, only unambiguously determined mutations were used. In addition, the AL and MM sequences that were to be under comparison with each other were trimmed to the same length. This concerns the N- as well as the C-terminus of the sequences. The sequences were also N-terminally constrained by analyzing only the region covered by the Vbase2 reference. To calculate the median mutation count, only the mutated segments were considered and the median was calculated only from

them. The MM120 sequence displayed an insertion of four AAs, which was in this analysis defined as one mutation. A deletion was also indicated as a mutation.

Besides the mutation distribution, individual positions were also analyzed. If not otherwise specified, only positions that displayed a mutation in  $\geq 50\%$  were defined as mutation hotspots. In this context, the total number was determined by only counting the ambiguously determined AA positions – in contrast to the calculation of the median mutation count and mutation frequency. Besides the AA exchange, the underlying cDNA nucleotide triplet was also investigated.

The IGLV2-14 MM and AL sequences were analyzed using the web-based tool LICTOR. LICTOR is an application for the prediction of amyloidogenicity of lambda LCs based on mutations (Garofalo et al. 2021).

#### 2.9.5 Amino Acid Composition Analysis

The sequences were trimmed as described in chapter 2.9.4. For analysis of the AA composition, the positions that could not be clearly determined were changed to the respective reference AA. Subsequently, an analysis was performed using the ExPASy "ProtParam" tool (Duvaud et al. 2021). For the purpose of conciseness, only differences  $\geq 0.5\%$  were mentioned in the text and differences  $>0.5\%$  were numerically specified.

#### 2.9.6 Biophysical Parameter Analysis

The sequences were trimmed as described in chapter 2.9.4 and for AA positions that could not be clearly determined the respective reference AA was used. The beta sheet aggregation tendency (AGG) value was calculated using TANGO (Rousseau et al. 2006). The grand average of hydropathicity (GRAVY) value was calculated using the ExPASy "ProtParam" tool (Duvaud et al. 2021). The molecular weight (Mw), as well as the isoelectric point (pI), were determined using the ExPASy "Compute pI/Mw" tool (Duvaud et al. 2021). Not only the pI but also the difference between the patient-derived LC and a reference LC was calculated ( $\Delta pI$ ). In this context, for each patient-derived LC, a reference with the respective IGLV, IGLJ, and IGLC segment as well as the patient-specific linker region was individually built. A not unambiguously determined AA in the linker region was neglected. For several patient-derived LC sequences, no clear assignment towards IGLJ2 and IGLJ3 was possible but the two respective reference sequences did not differ in pI. This also applies to sequences, which were not clearly assigned to IGLC2 or IGLC3. In the analyzed IGLC sections no difference between the two reference sequences can be defined on AA level.

### 2.9.7 Statistical Analysis and Data Visualization

The statistical analysis was performed using the IBM SPSS statistics program. If not otherwise indicated, values are presented as median.

The exact Fischer test (Fischer), two-tailored, or Chi-Quadrat test (Chi) were used to determine the significance levels of comparison for nominal data. For metric data normal distribution was tested using the Shapiro-Wilk normality test. If normal distribution was indicated in both independent subgroups, the significance level was calculated accordingly by using a two-tailored t-test (t-test). In this context, the variance equality was tested using the Levene-Test. Significance levels between independent subgroups and non-parametric data were calculated using a median test (Median) or two tailored Mann-Whitney U test (U-test). Significance values were adjusted by the Bonferroni correction for multiple tests per test-set. A p-value  $\leq 0.05$  was considered statistically significant and was numerically specified in the text. The differences concerning the mutation count and frequency were tested using the complete dataset without further separation concerning the frequency and mutation count. In addition, analysis and data visualization was performed using Excel, ChemSketch, WebLogo, R and R-studio using the “ggplot2” (Wickham 2016) and “ggsignif” (Ahlmann-Eltze and Patil 2021) packages.

The relative risk was calculated using the web-based MedCalc relative risk tool.

## 3 Results

### *Work program:*

Before analyzing the LC sequences themselves, the AL and MM cohorts are clinically characterized. In the next chapter, the composition of the MM samples is analyzed as the LC sequences of the MM patients were obtained using a different method. In the first chapter of the actual LC sequence analysis, the IGLV family and IGLV subfamily distribution are examined. From this point onwards, the analyses are performed not only for AL, MM, and the AL organ tropism but also for two additional parameters: the presence or absence of a clonal HC in the patient or a dFLC > or < 180 mg/L. Next, the linkage between the IGLJ and IGLC segments are analyzed first, and the composition of the complete LCs afterwards. Detailed sequence analyses are performed for IGLV subfamilies that are most frequently associated with AL and to which more than 10 AL sequences can be assigned: IGLV2-14, IGLV3-1, IGLV3-21, and IGLV6-57. Each IGLV subfamily is examined separately concerning patient characteristics, general mutation number and distribution within the LCs, specific mutations detected in the sequence alignment, the AA composition of the LC, and finally, various biophysical parameters. The analysis of IGLV3-21 deviates from this scheme; here, next-generation sequencing experiments were performed to investigate the sequence composition within the samples in more detail. The IGLV6-57 analysis has the particularity that IGLV2-23 sequences are used for comparison. Finally, the results are compared with each other, and the less frequently detected IGLV subfamilies are addressed less extensively. In the last step, the results from these rare IGLV subfamilies are compared with the previous ones.

### 3.1 Clinical Characteristics of the Cohorts

In the context of this study, 92 bone marrow samples of AL patients were processed. This concerns only samples from AL patients with a dominant heart (AL\_H) or dominant heart and kidney involvement (AL\_HK). This stratification was performed based on established criteria (chapter 2.4), to further investigate the AL organ tropism. However, the final AL cohort consisted of only 82 AL samples: 61 AL\_H and 21 AL\_HK. This loss of samples is because after the bone marrow CD138<sup>+</sup> cell sorting, these cells need to be used for an obligatory FISH analysis first. Afterwards, two samples corresponding to AL\_HK and nine samples corresponding to AL\_H did not contain enough CD138<sup>+</sup> cells for further analysis (**Table 15**).

In the final AL cohort, the bone marrow samples of the AL\_H and AL\_HK patients had a comparable median volume of 52 – 60 mL and contained an average of 0.5 % CD138<sup>+</sup> plasma

cells. In seven AL\_H cases, it was not possible to detect any CD138<sup>+</sup> plasma cells. However, it was assumed that enough cells and Ig LC RNA were available for further analysis due to a detection limit of 2.5e+04 cells in the CD138<sup>+</sup> cell sorting. For the 52 MM patients included in this study, no information about the initial volume of the bone marrow aspirate and CD138<sup>+</sup> cell ratio was available. Further information on the clonality of the CD138<sup>+</sup> samples was provided by the FISH analysis. In this context, the highest percentage measured was compared between cohorts. Here, the MM samples (98 %, range: 87 % – 100 %) displayed a significantly higher value than the AL\_H (90 %;  $p = 1.13e-08$  (Median)) and AL\_HK samples (86 %;  $p = 0.001$  (Median)) – implying a larger clonal size.

**Table 15. Comparison of CD138<sup>+</sup> cell-sorting and the main clone in the FISH analysis of AL amyloidosis patients.** The highest measured percentage of a genetic aberration in the FISH result was defined as the proportion of the main clone (Bochtler et al. 2018). FISH = fluorescence *in situ* hybridization, PC = plasma cells, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement. More detailed information about the investigator, the sample material, applied tests, and the reference areas are listed in chapter 2.4 and Table 14.

	AL_H n = 61	AL_HK n = 21
Median bone marrow aspirate volume [mL] (range)	52 (8 – 95)	60 (10 – 83)
Median percentage of CD138 <sup>+</sup> PC in the sample (range)	0.5 % (0 – 7)	0.5 % (0 – 12)
Number of cell sorts with no harvested CD138 <sup>+</sup> PC n (%)	7 (4 %)	0
Median percentage of the main clone in the FISH analysis (range)	90 % (43 – 98 %)	86 % (10 – 97 %)

When analyzing the clinical characteristics, only a few similarities can be noted between the cohorts (**Table 16**). AL\_H as well as AL\_HK and MM patients displayed a median age at diagnosis of about 64 – 65 years and most of the samples were obtained at diagnosis (AL\_H = 89 %, AL\_HK = 86 %, MM = 100 %). As a side note, five AL patients (3x AL\_H, 2x AL\_HK) also had a MM diagnosis (AL+MM) at the time point of bone marrow aspiration. Overall, the AL\_H and MM subgroups included more male than female patients (AL\_HK = male: 11, female: 10) which corresponds with the general epidemiology of the diseases. The AL\_H and MM cohorts also displayed a comparable median dFLC value, twice as high as the median dFLC value of the AL\_HK subgroup (AL\_H = 406 mg/L, AL\_HK = 169 mg/L, MM = 411 mg/L). While the AL\_H and AL\_HK subgroups displayed a comparable median plasma cell infiltration in the bone marrow of about 12 %, the MM subgroup showed a significantly higher median value of about 60 % (AL\_H vs. MM  $p = 3.00e-12$  (Median), AL\_HK vs. MM  $p = 0.000042$  (Median)). Regarding proteinuria, the

AL\_HK patients (3 g/d) displayed a significantly higher median value than the AL\_H (0.3 g/d;  $p = 2.00e-06$  (Median)) and MM cohort (1 g/d;  $p = <0.01$  (U-test)). In contrast, the AL\_H patients (91 U/L) displayed a higher AP value than the AL\_HK (68 U/L) and MM patients (70 U/L). No information about the GFR CKD-EPI, NT-proBNP, and hsTNT values of the MM patients were available. However, the AL\_H patients displayed a higher median NT-proBNP (7202 mg/L vs. 3361 mg/L) and GFR CKD-EPI value (71 mL/min/1.73 m<sup>2</sup> vs. 62 mL/min/1.73 m<sup>2</sup>) but a lower hsTNT value (70 µg/L vs. 76 µg/L) than AL\_HK patients.

A difference between the two diseases was also noted regarding the presence of a M-gradient, which was detected significantly more often in the MM than in AL patients (AL\_H = 42 %  $p = <0.001$  (Fischer), AL\_HK = 52 %  $p = <0.001$  (Fischer), MM = 87 %) (Table 16). Additionally, the AL\_HK and MM samples corresponded more often to a patient with detectable clonal HC in serum (AL\_H = 44 %; AL\_H vs. MM  $p = <0.001$  (Fischer), AL\_HK = 67 %, MM = 79 %). These HCs were identified as IgG in more than half of the cases for all subgroups (AL\_H = 22/27, AL\_HK = 8/14, MM = 33/41). The genetic aberration t(11;14), which is associated with a loss of the HC, was detected in 38 % of AL\_H patients, 48 % of AL\_HK patients, and 28 % of MM patients. A gain of 1q21 was detected less frequently in the MM than in the AL\_H subgroup (AL\_H = 37 %, AL\_HK = 33 %, MM = 29 %).

**Table 16. Overview of selected clinical characteristics of 82 AL amyloidosis and 52 multiple myeloma patients.** AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement. AL = AL amyloidosis patients, MM = multiple myeloma patients, LC = light chain, HC = heavy chain, IFE = immunofixation electrophoresis in serum, NA = not available, AL+MM = AL amyloidosis patients who were also diagnosed with multiple myeloma, GFR CKD-EPI = calculation of the glomerular filtration rate using the formula established by the Chronic Kidney Disease Epidemiology Collaboration, AP = alkaline phosphatase, dFLC = difference between disease-associated and uninvolved circulation free light chains, hsTNT = heart associated troponin T. More detailed information about the investigators, the sample material, applied tests, and reference area are listed in chapter 2.4 and Table 14.

### 3.2 Multiple Myeloma Sample Composition

Since the MM data was generated via a bulk RNA sequencing approach, the sequence composition of these samples was also analyzed (**Table 17**). This analysis was not performed for the AL sequences because Sanger sequencing is not suitable for unambiguously differentiating subsequences and especially not for providing an associated percentage. Concerning the MM data, only additional sequences that were detected in  $\geq 1\%$  were considered. It should be mentioned that in some cases several sequence sections were given due to the bioinformatic analysis. It is assumed that these sections result from variations at single positions and therefore lead to different sequence sections. This phenomenon will be addressed for each IGLV subfamily separately.

The sequence with the highest percentage (sequence\_A) showed a median percentage of 98.85 % (52.46 % – 99.98 %) (**Supplementary Information Table 2**). However, in 16 cases it was possible to detect a second abundant sequence (sequence\_B) with a median percentage of 23.54 % (1.23 % – 47.38 %). When a sequence\_B was detected, the corresponding sequence\_A showed a lower median percentage of 74.86 % (52.46 % – 98.13 %) (p = <0.001 (Median)).

When analyzing the sequences concerning the IGLV family usage, the samples with detectable sequence\_B cluster to the IGLV1 family, especially to IGLV1-44 (9/9) (**Table 17**). In general, it was possible to detect a sequence\_B in 64 % of the IGLV1 cases (9/14), 24 % of the IGLV2 cases (4/17), and 6 % of the IGLV3 cases (1/17) (**Table 17, Supplementary Information**

**Table 2).** Besides the higher prevalence, the IGLV1 family displayed also a higher percentage of the corresponding sequence\_B (IGLV1 = 25.98 %, IGLV2 = 4.28 %, IGLV3 = 1.23 %). This reflects in a lower median percentage of the respective sequence\_A (IGLV1 = 78.05 %, IGLV2 = 98.85 %, IGLV3 = 99.41 %). Two sequences were not assigned unambiguously to an IGLV family (sequence\_A = 74.57 % and 75.16 %) and displayed a sequence\_B with an especially high percentage (25.3 % and 21.79 %).

**Table 17. Sequence composition of multiple myeloma samples based on the bulk RNA sequencing results.** The sequence composition was analyzed concerning the detected IGLV families in the multiple myeloma cohort (n = 52). sequence\_A = sequence with the highest percentage >1 %, sequence\_B = sequence with the second highest percentage >1 %.

	n	Median percentage sequence_A (range)	Percentage of sequences with a sequence_B (n)	Median percentage of sequence_A with sequence_B (range)	Median percentage sequence_B (range)
IGLV1	14	78.05 (52.46 – 99.95)	64 (9/14)	73.61 (52.46 – 97.32)	25.98 (2.52 – 57.38)
IGLV2	17	98.85 (93.68 – 99.87)	24 (4/17)	94.61 (93.68 – 95.67)	4.28 (3.56 – 6.02)
IGLV3	17	99.41 (98.08 – 99.98)	6 (1/17)	98.13	1.23
IGLV6	1	99.83	0	0	0
IGLV7	1	99.78	0	0	0
NA	2	74.57, 75.16	100 (2/2)	74.57, 75.16	25.30, 21.79

When analyzing sequence\_B in more detail, eight out of nine IGLV1-44 sequences displayed the same IGLV, IGLJ, and IGLC segment composition as the corresponding sequence\_A. One sequence\_B was not clearly assigned to IGLV1-47 or IGLV1-44 but showed the same IGLJ and IGLC subfamilies as the corresponding sequence\_A. Regarding the IGLV2 family, one IGLV2-14 and one IGLV2-23 sequence displayed the same composition for sequence\_A and sequence\_B. However, it was not possible to assign any IGL segment due to several disconnected sequence sections two times (sequence\_A = IGLV2-23). The IGLV3 sequence showed an IGLV3-21/IGLJ2/IGLC2 linkage for both sequences.

Only sequence\_A was used in the following detailed IGLV subfamily analysis and comparison with the AL cohort.

### 3.3 IGL Family Distribution

#### 3.3.1 IGLV Family and Subfamily Distribution

To address the question, if some IGLV families display a higher amyloidogenic potential than others, a comparison between the AL and MM cohort was performed. In general, the IGLV3 family was identified as the most common AL IGLV subfamily (35 %) and one of the two most common MM IGLV families (33 %). IGLV2 was the second most common AL IGLV subfamily (AL = 22 %) and the other most common MM IGLV subfamily (MM = 33 %) (**Figure 11 A**). A difference was noted regarding the third most common IGLV family: the MM cohort displayed IGLV1 (MM = 27 %, AL = 11 %;  $p = <0.001$  (Fischer)), and the AL cohort IGLV6. Of note, IGLV6 was detected in 21 % of the AL cases and only once in the MM cohort (2 %;  $p = <0.001$  (Fischer)).

Overall, two rare IGLV families were exclusively detected in one of the cohorts: the IGLV7 family was assigned only once in the MM cohort (2 %), and the IGLV8 family once in the AL cohort (1 %; AL\_HK). Moreover, the AL IGLV8 sequence corresponded to one of the five AL patients who were also diagnosed with MM (FOR229\_HK). In addition, one AL+MM sequence each was assigned towards IGLV2 (IGLV2-14, FOR159), IGLV1 (IGLV1-44, FOR147), IGLV6 (FOR188\_HK) and IGLV3 (IGLV3-1, FOR123). Due to this equal distribution, the AL+MM subgroup was not investigated further (

#### Supplementary Information Table 3).

However, the IGLV family distribution was not only analyzed between AL and MM but also concerning the AL organ tropism. In this context, a difference was also noted regarding the IGLV6 family (**Figure 11 B**). IGLV6 was assigned in 38 % of the AL\_HK cases and significantly less often in AL\_H cases (15 %;  $p = 0.032$  (Fischer)). Contrastingly, IGLV3 was detected more often in the AL\_H than AL\_HK subgroup (43 % vs. 14 %;  $p = 0.032$  (Fischer)). IGLV2 (AL\_H = 21 %, AL\_HK = 24 %) and IGLV1 (AL\_H = 11 %, AL\_HK = 10 %) were detected in both AL subgroups in a comparable frequency.

Since not only IGLV families, but also IGLV subfamilies can be differentiated from each other, this was investigated in the next step. Here, the AL cohort displayed IGLV6-57 and the MM cohort IGLV3-21 (21 %, AL = 13 %) as the most common IGLV subfamily (**Figure 11 C**). The difference concerning the IGLV6 family has already been addressed since IGLV6-57 is the only detected IGLV6 subfamily (AL = 21 %, MM = 2 %;  $p = <0.001$  (Fischer)). IGLV2-14 was detected as one of the most common IGLV subfamilies in both diseases: AL second 20 %, MM third 15 %. For the IGLV1-44 subfamily large deviations were observed between AL and MM.

This family was detected in 6 % of the AL cohort and as the second most common MM IGLV subfamily (17 %). This was reversed in terms of IGLV3-1, which was detected as the third most common AL subfamily (18 %) and in only 6 % of the MM cohort. Furthermore, the IGLV2-23 subfamily was detected only in the MM cohort ( $p < 0.001$  (Fischer)) and – shared with IGLV2-14 – as the third most common IGLV subfamily (15 %).

Regarding the AL organ tropism, a difference was noted regarding IGLV3-21, which was identified as the third most common AL\_H IGLV subfamily with an overall three times higher percentage than in the AL\_HK subgroup (15 % vs. 5 %) (**Figure 11 D**). Besides the already addressed significantly higher IGLV6-57 AL\_HK than AL\_H association, it is noticeable that four out of eight AL\_HTX sequences were assigned to this subfamily. However, the AL\_HTX category does not describe an organ involvement, but a certain treatment option for a severe heart manifestation. Further, IGLV3-1 can be described as the most detected AL\_H (21 %) and third most detected AL\_HK IGLV subfamily (10 %). Both subgroups share IGLV2-14 as the second most used IGLV subfamily (AL\_H = 20 %, AL\_HK = 19 %).

**Figure 11. Comparison of the IGLV family and subfamily distribution between the AL amyloidosis and the multiple myeloma cohort as well as between the heart and heart and kidney organ tropism in AL amyloidosis.** A) Comparison of the IGLV family distribution between the AL amyloidosis and the multiple myeloma cohort. B) Comparison of the IGLV family distribution between the AL amyloidosis heart and heart and kidney organ tropism as well as the multiple myeloma cohort. C) Comparison of the IGLV subfamily distribution between the AL amyloidosis and the multiple myeloma cohort. D) Comparison of the IGLV subfamily distribution between the AL amyloidosis heart and heart and kidney organ tropism as well as the multiple myeloma cohort. AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart

and kidney involvement, NA = not clearly assigned IGLV family, \* =  $p \leq 0.05$ ; AL n = 82, MM n = 52, AL\_H n = 61, AL\_HK n = 21.

To summarize, in the analysis concerning the IGLV family distribution, a prominent difference was noted regarding IGLV6-57. This IGLV family was detected more frequently in AL than MM and AL\_HK than AL\_H. In contrast, IGLV1 was detected more frequently in the MM than AL cohort, and IGLV3-1 was more frequently in the AL\_H than AL\_HK cohort. Finally, IGLV2-23 was only detected in the MM cohort.

**Parenthesis:** An additional analysis was performed to evaluate the effect of a potential HC binding partner and the size and malignancy of the B cell clone. In this context, the sequences were stratified concerning a present clonal heavy chain in serum and a dFLC >180 mg/L in the respective patients (Figure 12). This stratification was performed for IGLV subfamilies that were most frequently associated with AL and to which more than 10 AL sequences were assigned. This concern: IGLV2-14 (AL n = 16, MM n = 8), IGLV3-1 (AL n = 15, MM n = 3), IGLV3-21 (AL n = 10, MM n = 11) and IGLV6-57 (AL n = 17, MM n = 1). In general, the sub-analyses were performed, when more than one sequence can be assigned to one of the respective subgroups.

When stratifying the AL cases for the presence (HC) or absence of a clonal HC (no HC), the IGLV2-14 and IGLV6-57 subfamily displayed an association with AL HC cases (IGLV2-14: 29 % vs. 11 %; IGLV6-57: 27 % vs. 13 %) (Figure 12 A). Interestingly, a certain organ tropism was noted – for AL\_H IGLV2-14 sequences an HC association was detected with a six times higher percentage than for no HC cases (37 % vs. 6 %;  $p = 0.051$  (Fischer)). In contrast, AL\_HK IGLV2-14 sequences were associated towards no HC cases twice as often than towards HC cases (29 % vs. 14 %). Regarding the IGLV6-57 family, an AL\_HK HC association was detected in 50 % of the cases, and only in 14 % of AL\_HK no HC cases. However, a comparable percentage was noted in the AL\_H subgroup (AL\_H HC = 15 %, AL\_H no HC = 13 %) (Figure 12 B). Concerning the MM cohort, the MM IGLV3-21 and IGLV2-14 sequences displayed an association with HC cases (IGLV3-21: 24 % vs. 9 %; IGLV2-14: 17 % vs. 9 %), which was similar to the AL cohort.

When analyzing the sequences with respect to a dFLC >180mg/L, no similarities between the two diseases were noted (Figure 12 C). The AL IGLV3-1 and IGLV3-21 sequences were more frequently detected for LCs corresponding to patients with a dFLC >180 mg/L (> dFLC) (IGLV3-1: 27 % vs. 4 %;  $p = 0.014$  (Fischer); IGLV3-21: 14 % vs. 7 %). Contrastingly, AL

IGLV6-57 sequences displayed an association with a dFLC <180 mg/L (< dFLC) (14 % vs. 33 %). Again, a difference regarding the organ tropism was noted – the AL\_H IGLV6-57 sequences showed an < dFLC association (33 % vs. 7 %;  $p = 0.024$  (Fischer)), and the AL\_H IGLV2-14 and IGLV3-1 sequences towards > dFLC (IGLV2-14 = 24 % vs. 13 %; IGLV3-1 = 29 % vs. 7 %) (Figure 12 D). In contrast, AL\_HK IGLV2-14 sequences showed a < dFLC association (11 % vs. 25 %).

Addressing the MM cohort, IGLV1-44 sequences showed an association towards > dFLC cases (26 % vs. 0 %). This was also the case for MM IGLV2-14 sequences (20 % vs. 6 %), similar to the AL\_H subgroup. For MM IGLV3-1 and IGLV3-21 sequences an association towards < dFLC cases was noted (IGLV3-1: 3 % vs. 13 %; IGLV3-21: 11 % vs. 38 %).

**Figure 12. Comparison of the IGLV subfamily distribution between the AL amyloidosis and the multiple myeloma cohort and the presence or absence of a clonal heavy chain or a dFLC >180 mg/L.** Analysis of the four IGLV subfamilies with at least ten assigned AL amyloidosis light chain sequences. A) Comparison of the IGLV subfamily distribution between the AL amyloidosis and the multiple myeloma cohort with respect to a present heavy chain. B) Comparison of the IGLV subfamily distribution between AL amyloidosis patients with dominant heart or dominant heart and kidney involvement with respect to a present heavy chain. C) Comparison of the IGLV subfamily distribution between the AL amyloidosis and the multiple myeloma cohort with respect to a dFLC >180 mg/L. D) Comparison of the IGLV subfamily distribution between AL amyloidosis patients with dominant heart or dominant heart and kidney involvement with respect to a dFLC >180 mg/L. AL = AL amyloidosis patients, MM = multiple myeloma patients, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L; AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, \* =  $p \leq 0.05$ , AL HC n = 41, AL no HC n = 38, AL > dFLC n = 51, AL < dFLC n = 27, MM HC n = 41, MM no HC n = 11, MM > dFLC n = 35, MM < dFLC n = 16, AL\_H HC n = 27, AL\_H no HC n = 31, AL\_H > dFLC n = 42, AL\_H < dFLC n = 15, AL\_HK HC n = 14, AL\_HK no HC n = 7, AL\_HK > dFLC n = 9, AL\_HK < dFLC n = 12.

To summarize, IGLV2-14 was significantly more frequently detected in AL\_H HC than in AL\_H no HC sequences. Concerning the dFLC, IGLV3-1 was significantly more frequently detected in AL > dFLC than AL < dFLC sequences, and IGLV6-57 was significantly more frequent in AL\_H < dFLC than AL\_H > dFLC sequences.

### 3.3.2 IGLJ and IGLC Family Distribution

Not only the IGLV distribution but also the composition of the complete LC was evaluated and, in this context, also the IGLJ/IGLC linkage. When considering only the unambiguously determined IGLJ and IGLC segments for both diseases, IGLJ1, IGLJ2, and IGLJ7 were only detected in connection with the corresponding IGLC segment (**Table 18**). In contrast, IGLJ3 was detected in linkage with both IGLC2 and IGLC3. As a side note, when additionally analyzing the AA sequences with the IMGT/DomainGapAlign tool IGLC2\*01, IGLC2\*02 and IGLC3\*04 are all indicated with a 100 % identity.

In general, both diseases displayed an IGLV-IGLJ2/IGLC2 linkage in most of the cases (AL = 38 %; MM = 42 %), second most common towards IGLJ3/IGLC3 (AL = 22 %, MM = 13 %) and third most common towards IGLJ1/IGLC1 (AL = 13 %; MM = 10 %) (**Table 18**). This order was also detected when stratifying the AL sequences with respect to the organ involvement or a present potential HC binding partner, as well as for the MM HC and MM dFLC subgroups. A difference was noted in the AL < dFLC sequences, which presented an IGLJ2/IGLC2 and IGLJ3/IGLC3 linkage with the same frequencies (27 %). In contrast, for AL > dFLC sequences an IGLJ2/IGLC2 linkage was observed in 45 % of the cases and IGLJ3/IGLC3 in only 18 %.

**Table 18. IGLJ and IGLC family linkage and distribution between the AL amyloidosis and multiple myeloma cohort.** Only detected linkages are shown. AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L, J = IGLJ, C = IGLC, NA = not clearly assigned, bold = most common linkage. For three AL amyloidosis patients no information about the heavy chain was available, as well as for five AL amyloidosis and one multiple myeloma patients about the dFLC.

IGLJ	1	2		3			2/3			7	7/3	NA
IGLC	1	2	2_3	2	3	2_3	2	3	2_3	7	2	
AL n = 82 [%]	13	<b>38</b>	0	7	22	0	2	5	0	1	1	10
AL_H n = 61 [%]	16	<b>34</b>	0	8	18	0	3	7	0	2	2	10
AL_HK n = 21 [%]	5	<b>48</b>	0	5	33	0	0	0	0	0	0	10
MM n = 52 [%]	10	<b>42</b>	8	2	13	8	6	4	2	2	0	4
AL HC n = 41 [%]	15	<b>37</b>	0	5	24	0	2	7	0	2	2	5
AL no HC n = 38 [%]	13	<b>37</b>	0	11	16	0	3	3	0	0	0	16

IGLJ	1	2		3			2/3			7	7/3	NA
IGLC	1	2	2_3	2	3	2_3	2	3	2_3	7	2	
MM HC n = 41 [%]	10	<b>41</b>	7	2	15	7	7	5	0	0	0	5
MM no HC n = 11 [%]	9	<b>46</b>	9	0	9	9	9	0	9	9	0	0
AL > dFLC n = 51 [%]	14	<b>45</b>	0	6	18	0	2	4	0	2	2	8
AL < dFLC n = 26 [%]	15	<b>26</b>	0	11	<b>26</b>	0	0	7	0	0	0	15
MM > dFLC n = 36 [%]	8	<b>36</b>	8	3	14	8	8	3	3	3	0	6
MM < dFLC n = 16 [%]	13	<b>50</b>	6	0	13	6	6	6	0	0	0	0

To summarize, an IGLJ2/IGLC2 connection was detected as the most common linkage in almost all cohorts and subgroups. The only exception was noted for the AL > dFLC subgroup which displayed an IGLJ2/IGLC2 and IGLJ3/IGLC3 linkage equally frequent.

### 3.3.3 Composition of the IGLV, IGLJ, and IGLC Segments

In the next step, not only the IGLJ/IGLC linkage but also the connection with an IGLV segment was investigated. Again, the five most common AL IGLV subfamilies were analyzed.

Regarding the IGLV2-14 subfamily, the AL (6/16) and MM (5/8) sequences displayed a linkage with IGLJ2/IGLC2 most often (**Table 19**). In addition, the AL\_H sequences showed an IGLV2-14 IGLJ1/IGLC1 linkage in five out of twelve cases and none of the AL\_HK sequences (n = 4). In contrast, the AL\_HK sequences presented more often an IGLJ2/IGLC2 linkage than the AL\_H sequences (3/4 vs. 3/12). When stratifying for a present clonal HC or dFLC, the IGLV2-14 AL HC and > dFLC sequences showed an IGLJ1/IGLC1 linkage more frequently than the respective other subgroup (both = 5/12 vs. 1/4). Regarding the MM dFLC subgroups, no pattern was observed and only one MM sequence corresponded to the MM no HC subgroup. In the IGLV3-1 subfamily, an IGLJ2/IGLC2 linkage was also overserved with the highest frequency in the AL cohort (9/15) with no deviation when stratifying for dominant organ involvement. However, the MM sequences displayed an IGLJ1/IGLC1 linkage in two out of three cases (**Table 19**). In the analysis regarding a clonal HC, the AL no HC sequences showed an IGLJ2/IGLC2 linkage more often than the AL HC subgroup (6/8 vs. 2/6). An analysis regarding the dFLC was not performed since only one AL sequence corresponded to the < dFLC subgroup.

In comparison to the other subfamilies, a difference regarding the most common IGLJ/IGLC linkage was noted in the IGLV3-21 subfamily (**Table 19**). The corresponding AL (n = 10, AL\_HK n = 1) sequences displayed a linkage to IGLJ2/IGLC2 and IGLJ3/IGLC3 in four cases each, while the MM IGLV3-21 sequences showed a prominent linkage to IGLJ2/IGLC2 (7/11). While the AL HC sequences more often showed an IGLJ2/IGLC2 linkage (3/5 vs. 1/6), an IGLJ3/IGLC3 linkage was detected more frequently in the AL no HC sequences (0/4 vs. 4/6).

Only two AL sequences corresponded to the < dFLC subgroup but both showed an IGLJ2/IGLC2 linkage. Regarding the MM dFLC subgroups, no pattern was observed, and only one MM sequence corresponded to the MM no HC subgroup.

A generally preferred IGLJ2/IGLC2 linkage was also noted in the AL IGLV6-57 sequences (8/17; MM n = 1 IGLJ3/IGC3) (**Table 19**) and no difference was noted regarding the organ tropism. However, a higher frequency of IGLJ3/IGLC3 was observed for the AL HC compared to the AL no HC subgroup (4/11 vs. 0/6) as well as a more preferred IGLJ2/IGLC2 linkage in the AL > dFLC than the AL < dFLC subgroup (5/9 vs. 3/9).

**Table 19. Overview of the five most common IGLV segments and the IGLJ/IGLC linkages between the AL amyloidosis and multiple myeloma cohort.** Only detected linkages are shown. AL = AL amyloidosis patients, MM = multiple myeloma patients, NA = not clearly assigned, bold = most common linkage.

IGLJ	1	2		3			2_3			7	7_3	NA
IGLC	1	2	2_3	2	3	2_3	2	3	2_3	7	2	
AL n = 82, n	11	<b>31</b>	0	6	18	0	2	4	0	1	1	8
MM n = 52, n	5	<b>22</b>	4	1	7	4	4	2	1	1	0	2
IGLV2-14												
AL n = 16, n	5	<b>6</b>	0	0	3	0	0	2	0	0	0	
MM n = 8, n	1	<b>5</b>	0	0	0	2	0	0	0	0	0	-
IGLV3-1												
AL n = 15, n	3	<b>9</b>	0	1	1	0	0	0	0	1	0	-
MM n = 3, n	<b>2</b>	1	0	0	0	0	0	0	0	0	0	-
IGLV3-21												
AL n = 10, n	0	<b>4</b>	0	0	<b>4</b>	0	1	1	0	0	0	-
MM n = 11, n	1	<b>7</b>	0	0	1	1	1	0	0	0	0	-
IGLV6-57												
AL n = 17, n	0	<b>8</b>	0	3	5	0	0	1	0	0	0	-
MM n = 1, n	0	0	0	0	1	0	0	0	0	0	0	-

When analyzing the AL IGLJ1/IGLC1 (AL n = 11, MM n = 5) frequency separately, a linkage was most noted with IGLV2-14 (5/11) and IGLV3-1 (3/11; MM = 2/3). An AL IGLJ2/IGLC2 linkage was most detected with IGLV3-1 (9/31) and IGLV6-57 (8/31). The MM IGLJ2/IGLC2 sequences displayed most frequently a linkage with IGLV3-21 (7/22) and IGLV2-14 (5/22). The AL IGLJ3/IGLC3 linkage was assigned in 5/18 cases towards IGLV6-57 and 4/10 cases towards IGLV3-21. Regarding the IGLJ3/IGLC3 MM sequences, no favored linkage was noted.

To shortly summarize, for IGLV2-14 the MM and AL sequences presented most frequently and IGLJ2/IGLC2 linkage. This was also the case for the IGLV6-57 AL, IGLV3-1 AL and IGLV3-21 MM sequences. In contrast, the IGLV3-21 AL sequences presented equally frequent an IGLJ2/IGLC2 or an IGLJ3/IGLC3 linkage.

**Parenthesis:** In the following, the four IGLV subfamilies with at least ten assigned AL amyloidosis sequences were analyzed in a more detailed manner (IGLV2-14, IGLV3-1, IGLV3-21, IGLV6-57). In this context, the overall mutation frequency and count were addressed, and detailed analyses of sequence alignments were performed. This sequence analysis especially concerned positions that were mutated in at least 50 % of the cases. The impact of the detected mutations was then studied in terms of the overall amino acid composition and various biophysical parameters. In addition, subgroup analyses regarding the influence of a potential clonal heavy chain binding partner and the size and malignancy of the B cell clone, in the context of a dFLC >180 mg/L, as well as the AL organ involvement were performed.

### 3.4 IGLV2-14

IGLV2-14 was detected as the second most common AL subfamily and one of two third most common MM IGLV subfamilies. In general, this subfamily comprised twelve AL\_H sequences (1x AL\_HTX), four AL\_HK sequences, and eight MM sequences (**Table 20**). The AL sequences FOR171 and FOR173 were not used for further analysis due to more than ten AAs that could not be clearly determined. These ambiguously defined AAs results from positions that showed a signal for two or more nucleotides in the Sanger sequencing; consequently, a blur was indicated at these positions.

An additional verification step was included since the AL and MM sequences were generated through different sequencing approaches. To guarantee comparability of the sequences four MM sequences (MM103, MM136, MM129, MM130) were additionally Sanger sequenced and the dominant signals were consistent with the respective sequences in all cases (**Supplementary Information Figure 8, Supplementary Information Figure 9, Supplementary Information Figure 10, Supplementary Information Figure 11**).

#### 3.4.1 Subgroup Analysis

Most AL IGLV2-14 sequences corresponded to patients with a detectable clonal HC in serum (12/16, 11x IgG, 1x IgA) and/or with a dFLC >180 mg/L (11/16) (**Table 20**). Also, seven out of eight MM patients displayed a detectable clonal HC (5x IgG, 1x IgA, 1x IgM) and/or a dFLC >180 mg/L. In context of the presented HC classes, the distribution is well in line with the approximate percentage of the total Ig in the adult serum (Lefranc and Lefranc 2020). Due to the uniform clinical presentation of MM patients with an IGLV2-14 LC, subgroup analyses were only performed for the AL cohort.

**Table 20. Overview of selected characteristics of 16 AL amyloidosis and 8 multiple myeloma patients with IGLV2-14 assigned light chain sequences.** The column "X AA [n]" defines how many amino acids were not determined unambiguously. Organ inv. = dominant organ involvement of AL amyloidosis patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, AL\_HTX = AL amyloidosis patients who received a heart transplant, AA = amino acid, AL = AL amyloidosis, MM = multiple myeloma, HC in IFE = detectable clonal heavy chain in the immunofixation electrophoresis in serum.

### 3.4.2 Mutation Frequency and Count

*To examine whether the difference in LC behavior is based on a difference in the general mutation distribution and frequency, these aspects were analyzed within the IGL segments.*

The MM sequences presented a significantly higher mutational load in the IGLV segment than the AL sequences (11.5 vs. 8.5,  $p = 0.026$  (Median), reference = 97 AA), but no prominent difference was observed regarding the IGLJ and IGLC segment (**Table 21**).

When analyzing the AL sequences for the organ tropism, a higher mutational load in the IGLV (9.5 vs. 7.5,  $p = 0.048$  (Median)) and IGLJ segment (2.0 vs. 1.0, reference = 12 AA) was detected in the AL\_HK sequences than the AL\_H sequences (**Table 21**). This difference was especially prominent in FR1 (20 % vs. 75 %) and FR3 (3.0 vs. 1.0, reference = 32 AA). Interestingly, FR1 was detected as the most conserved region in the AL and MM cohort.

When stratifying the AL sequences for the presence or absence of a clonal HC binding partner, the IGLV (9.0 vs. 7.0) and IGLJ segments of AL HC sequences showed a mutation more often (82 % vs. 33 %) – this was particularly observed in the CDR regions (CDR1, CDR2, and CDR3 = 91 % vs. 67 %) (**Table 21**).

In the analysis regarding the dFLC, AL > dFLC sequences presented a higher mutational load in the IGLV segment (9.0 vs. 8.0), and all sequences with a mutation in the IGLC segment were assigned to this subgroup (18 % vs. 0 %). In addition, a higher mutation frequency in CDR1 was detected in the AL > dFLC sequences (91 % vs. 67 %) (**Table 21**).

**Table 21. Comparison of the percentage of mutated IGL segments and average mutation count between AL amyloidosis and multiple myeloma IGLV2-14 assigned light chain sequences.**

The analysis was also performed with respect to different subgroups. AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, CDR = complementary determining region, FR = framework region, AA = amino acid, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L, \* = p ≤ 0.05, differences greater than 30 % and one (segments) or two (regions) additional mutations are marked in bold. FOR171, FOR173, and FOR201 were excluded, due to several ambiguously defined amino acids. The median mutation values were calculated using only the mutated segments/regions. The significance level was determined using the complete dataset. The Vbase2 IGLV2-14 reference sequence was used for calculations and the IGLC reference was trimmed at the C-terminus. The CDR3 region includes also the patient-specific linker region and the first two amino acids of the IGLJ segment and therefore spans 9-12 amino acids.

## 3.4.3 Sequence Alignment

*A more detailed analysis of the LC sequences was performed on AA level to identify potential unique mutations or mutation patterns that could influence the biochemical properties of the LC itself or discriminate the subgroups. This was carried out in a step-wise procedure. First, general sequence characteristics such as mutation hotspots (mutations >50 %) and their location were identified separately for both diseases. Then the hotspots were analyzed in terms of an exchange towards a specific AA or AAs with the same side chain properties and the respective cDNA. In this analysis, the LC sequences with more than ten unambiguously determined AAs (marked as X) were included.*

The higher overall mutation count in the MM sequences did also reflect in more mutation hotspots in the IGLV segment (9 vs. 3) (**Figure 13 A**). The AL sequences only presented two hotspots, which were restricted to a CDR region and shared by the MM sequences: 54S (CDR2, AL = AL = 11/16, MM = 6/8) and 96S (CDR3, AL = 8/16, MM = 5/8). Additional MM hotspots were defined at the following positions: 29V (CDR1, 4/8), 31G (CDR1, 4/8), 49M (FR2, 6/8), 62N (FR3, 6/8), 94T (CDR3, 4/8), 95S (CDR3, 5/8), and 97S (CDR3, 6/8).

The shared mutation hotspot 54S (3<sup>rd</sup> position CDR2) is the most frequently mutated position (AL = 11/16, MM = 6/8) and both diseases showed an exchange towards threonine in most of the cases (AL = 7/11; MM = 4/6; cDNA = AGT→ACT) (**Figure 13 A**). Additionally, a preferential exchange towards threonine was also noted for the second shared hotspots in the CDR3 (S96). In general, the 96S mutation was detected more frequently in AL\_HK (3/4) than in AL\_H sequences (5/12). Interestingly, the AL\_HK sequences presented an S96T mutation in three out of four cases and the same sequences presented a mutation at the eighth (K) or ninth (L or V) position of the IGLJ segment towards methionine (1x X with methionine or leucine as possibilities). This was not detected in the AL\_H or MM sequences.

In the following, the additional hotspots are analyzed chronologically (**Figure 13 A**). At position 29V, the MM sequences presented exclusively a mutation towards isoleucine (MM = 4/8, AL = 3/16, 1x X; cDNA = GTT→ATT). Position 31G was described as a MM mutation hotspot (4/8) but was also found frequently mutated in the AL sequences (7/16). An exchange towards the negatively charged AA aspartic acid was detected twice in the MM sequences and three times in the AL sequences (cDNA = GGT→GAT). The 49M MM mutation hotspot (6/8) was also found frequently mutated in the AL sequences (7/16, 6x AL\_H, 1x AL\_HK), with a prominent exchange for both diseases towards isoleucine (AL = 5/7, MM = 4/6; cDNA = ATG→ATX). At position 62N, the MM sequences presented a mutation in 6/8 cases but with no directed exchange pattern. Interestingly, the AL sequences showed at this position 5/16 times an exchange towards the negatively charged AA aspartic acid

(MM = 2/6; cDNA = AAT→GAT). Regarding the CDR3 MM hotspot 94T, a most prominent exchange towards serine was noted (MM = 3/4, AL = 0/4; cDNA = exchange at the first nucleotide or the second nucleotide in the triplet). No exchange pattern was detected regarding the 95S MM mutation hotspot, but at position 97S (6/8, AL = 7/16 1x X) an exchange towards threonine was detected in three out of six cases.

For the sake of completeness, it should be mentioned that the MM sequences showed a L-13F (cDNA = CTC→TTC) mutation in the leader region in five cases, but due to the oligonucleotide binding site, this region was not covered by the AL sequences.

In general, no consistent IGLV-IGLJ linker region was noted despite an overlapping Ensembl IGLV2-14 reference (**Figure 13 A**). Interestingly, the AL sequences presented a mutation at the first position of the IGLJ segment in seven out of sixteen cases (AL\_H = 6/12, AL\_HK = 1/4) and the MM sequences in three out of eight cases. For the AL sequences, a mutation towards leucine was detected four times and once in the MM sequences (**Figure 13 A**).

When stratifying the sequences for a potential clonal HC binding partner, only one IGLV position is remarkable. Two out of three AL no HC sequences displayed a H41N mutation, which was not detected in any other sequence (**Figure 13 B**). In addition, two AL no HC sequences presented additional prolines in the linker region (FOR124\_H = TPP, FOR225\_HK = P) – this was only detected once in the AL HC sequences (FOR101\_H = IP). No obvious mutation pattern was detected when stratifying for a dFLC >180 mg/L.

**Figure 13. Sequence sections of IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences.** A) Sequence sections of IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences B) Sequence sections of IGLV2-14 assigned AL amyloidosis light chain sequences corresponding to patients without detectable clonal heavy chain in serum. Bold = reference sequences, underlined = CDR regions, red highlight = discrepancy between the VBase2 and Ensembl IGLV2-14 reference, red letter = mutation, purple highlight = mutation hotspot, blue highlight = interesting mutation, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patients, AL = AL amyloidosis patients, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant. Only one IGLC reference is shown since the first amino acid can be defined as glycine in all cases. Amino acids were numbered according to the VBase2 reference. The complete amino acid sequence alignment is shown in Supplementary Information Figure 12. The complete cDNA sequence alignment is shown in Supplementary Information Figure 13.

Overall, it is noticeable that several regions showed specific mutation patterns (Figure 13 A). The CDR1 region of AL sequences presented an additional charge in half of the cases (MM = 3/8) and in the remaining AL sequences an accumulation of glycine (4/8) or asparagine

(4/8, MM = 1x) in the CDR3. Only one AL and MM sequence showed an additional charge in the CDR1 region and an additional glycine in the CDR3 (Asparagine = 2x AL, 1x MM). It is also worth mentioning that more than half of the MM sequences presented an insertion of at least one additional charge in the CDR3 region (MM = 5/8; AL = 2/16,  $p = 0.021$  (Fischer)).

Interestingly, these MM sequences corresponded in four out of five cases to a sequence, which displayed a M49 as well as a 54S mutation (AL  $n = 1$ ). In contrast, a higher content of small AAs like glycine, alanine, or proline was noted in the CDR3 region of AL than MM sequences (**Figure 14**).

**Figure 14. Comparison between the amino acid probability in the CDR3 region of IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences.** AL = AL amyloidosis patients, MM = multiple myeloma patients, red letter = negatively charged amino acid, green letter = positively charged amino acid, yellow letter = small amino acids glycine, proline, and alanine. Amino acid numbers were assigned according to the VBase2 IGLV2-14 reference. The linker region spans positions 98-100, the IGLJ segments start at position 101. If only one or two amino acids were detected in the linker region, this is indicated by the width of the letter.

#### 3.4.4 Amino Acid Composition

*The overall percentage of the individual AAs was calculated to evaluate the effect of the detected mutations and mutation patterns and to get an overview of the overall LC composition. Only differences  $\geq 0.5\%$  are mentioned in the following, differences  $> 0.5\%$  are numerically specified.*

The detected differences in the CDR3 region of MM and AL sequences did also reflect in the overall AA composition. The AL sequences displayed a higher amount of glycine, the MM sequences a higher amount of the positively charged AA arginine. In addition, a median percentage of methionine was detected in the AL sequences, which was not the case in the MM sequences (**Supplementary Information Table 4**).

When analyzing the sequences concerning the AL organ tropism, several differences were noticed (**Figure 15**). The AL\_H sequences displayed a higher amount of serine (17.0 % vs. 15.7 %) and threonine (9.9 % vs. 9.0 %) than the AL\_HK sequences. In addition, a higher

amount of aspartic acid, leucine, and a lower amount of asparagine (3.2 % vs. 4.0 %) and glutamic acid was detected in AL\_H than in AL\_HK sequences.

**Figure 15. Comparison of the overall amino acid percentage of threonine, asparagine, and serine in the IGLV2-14 light chain sequences between the AL amyloidosis organ tropism and the multiple myeloma cohort.** The amino acid percentage was calculated using the complete trimmed light chain sequence. MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement.

Stratifying the sequences for the presence or absence of a clonal HC, a higher amount of leucine, tyrosine, and valine was detected in the AL HC sequences than in the AL no HC sequences. In contrast, a higher amount of serine (17.5 % vs. 16.9 %) and especially asparagine (4.2 % vs. 3.2 %) was noted in the AL no HC sequences (**Figure 16**).

The AL sequences corresponding to patients with a dFLC >180mg/L showed a higher amount of alanine, asparagine, aspartic acid, isoleucine, tyrosine, and leucine (6.9 % vs. 6.4 %,  $p = 0.051$  (U-test)). The AL < dFLC sequences showed a higher percentage of arginine, glycine, valine, and especially threonine (9.0 % vs. 10.2 %) (**Figure 16**).

**Figure 16. Comparison of the overall amino acid percentage of asparagine and threonine in IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences with respect to the presence or absence of a clonal heavy chain or a dFLC >180 mg/L.** (A) Comparison of the overall amino acid percentage of asparagine and threonine in IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences, when stratifying for the presence of a clonal heavy chain in serum (B) Comparison of the overall amino acid percentage of asparagine and threonine in IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences when stratifying for a dFLC >180 mg/L. The amino acid percentage was calculated using the complete trimmed light chain sequence. MM = multiple myeloma patients, AL = AL amyloidosis patients, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L.

### 3.4.5 Biophysical Parameters

Several parameters were calculated to evaluate the effect of the mutations and amino acid composition on the biophysical properties of the LCs. The AGG parameter was included to determine the tendency for a beta sheet aggregation. The grand average of hydrophobicity (GRAVY) value is defined by the sum of hydrophobicity values of all AA divided by the protein length. A negative GRAVY-value indicates a hydrophilic nature and a possible interaction of the linear protein with water molecules. The pI was also calculated to examine the theoretical stability of the LCs. In this context, the pI of the patient-derived LCs itself and the difference in comparison to a reference sequence ( $\Delta pI$ ) was calculated. This was performed for the complete LC (IGLVJC) and the IGLV and IGLJ segments (IGLVJ). In addition, the average molecular weight ( $M_w$ ) of the LCs was specified.

Regarding the AGG value, the MM sequences presented a higher value than the AL sequences (1012.4 vs. 803.8) but no difference was noted when stratifying the AL sequences for dominant organ involvement (Table 22). In contrast, the AL HC sequences (830.1 vs. 753.0,  $p = 0.018$  (U-test)) as well as the AL > dFLC sequences (828.1 vs. 741.1) showed a higher value than the respective other subgroup.

In the analysis of the GRAVY score, the AL sequences showed a lower score than the MM sequences (-0.284 vs. -0.264) – this was especially evident in the AL\_HK sequences (-0.292). No differences were noted when stratifying for the presence of a clonal HC binding partner or dFLC (Table 22).

When analyzing the pI and  $\Delta$ pI of the complete LC and the IGLVJ-segments, a higher value of the MM than AL sequences was noted in all cases (pI: IGLVJC = 6.77 vs. 6.59, IGLVJ = 6.41 vs. 5.92;  $\Delta$ pI: IGLVJC = -0.32 vs. -0.50, IGLVJ = -0.34 vs. -0.70) (Table 22). Analyzing the AL sequences with respect to the organ involvement, the AL\_HK sequences presented a higher pI IGLVJ (6.03 vs. 5.85;  $\Delta$ pI IGLVJ -0.72 vs. -0.61) but a lower pI IGLVJC (6.15 vs. 6.76;  $\Delta$ pI IGLVJ -0.70 vs. -0.33) than AL\_H sequences. When stratifying the sequences concerning a potential HC binding partner, the AL HC subgroup presented a higher pI than the AL no HC subgroup (pI IGLVJC 6.76 vs. 6.42, pI IGLVJ 6.04 vs. 5.61). AL no HC sequences showed a lower median  $\Delta$ pI in the IGLVJ segments (-1.13 vs. -0.70) but a higher  $\Delta$ pI IGLVJC (-0.34 vs. -0.65) than the AL HC sequences. The AL > dFLC sequences displayed a higher pI IGLVJC (6.76 vs. 6.42) and lower pI IGLVJ (5.64 vs. 6.26). In both cases, the  $\Delta$ pI was lower than in the AL < dFLC sequences ( $\Delta$ pI IGLVJC: -0.88 vs. -0.34,  $\Delta$ pI IGLVJ -0.94 vs. -0.49). In summary, a stringent tendency towards a higher pI was only noted in the MM than AL and AL HC than AL no HC cohorts.

The MM sequences also presented a higher Mw than the AL sequences (19655 vs. 19580), which was also noted in the AL\_HK sequences in comparison to the AL\_H sequences (19751 vs. 19542) (Table 22). No difference was detected when considering a clonal HC binding partner but the AL > dFLC sequences presented a higher Mw than the AL < dFLC sequences (19630 vs. 19539).

**Table 22. Overview and comparison between different biophysical parameters of IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences and between different subgroups.** AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L, AGG =  $\beta$ -sheet aggregation tendency, GRAVY = grand average of hydropathicity, pI = isoelectric point,  $\Delta$ pI = difference between light chain sequence and respective reference sequence, IGLVJC = trimmed full-length light chain, IGLVJ = connected IGLV and IGLJ segments, Mw = average molecular weight, \* =  $p \leq 0.05$ .

	median AGG	median GRAVY	median pI IGLVJC	median $\Delta$ pI IGLVJC	median pI IGLVJ	median $\Delta$ pI IGLVJ	median Mw (average)

### 3.4.6 Summary IGLV2-14

IGLV2-14 was one of the most frequently detected IGLV subfamilies in the AL (second, 20 %, n = 16) and MM cohort (third, 15 %, n = 8). Both diseases displayed an IGLJ2/IGLC2 linkage in most of the cases, but the AL sequences presented an IGLJ1/IGLC1 linkage more often than the MM sequences (5/16 vs. 1/8). In addition, an association with the presence of a HC was noted for both diseases and for the MM cohort also towards a dFLC >180 mg/L.

Of note, MM sequences presented a significantly higher median mutation count in the IGLV segment than AL sequences (11.5 vs. 8.5, p = 0.026) which further resulted in more mutational hotspots (9 vs. 2). The two AL-associated hotspots were restricted to a CDR region and shared by the MM cohort. In more detail, position S54 (third position CDR2) was one of the most frequently mutated MM positions and the most frequently mutated AL position. In contrast, for the hotspot position 62N, a difference was detected between the two diseases. While six out of eight MM sequences presented a mutation to various AAs, five out of sixteen AL sequences displayed a mutation towards the negatively charged AA aspartic acid (MM = 2x). Besides the mutation hotspots, several regions presented variations. For example, the CDR1 region of AL sequences showed an additional charge in half of the cases (MM = 3/8), and the other half showed equally distributed an additional glycine or asparagine in the CDR3 (MM = 1x N). More generally, the CDR3 region of AL sequences displayed a tendency towards small AAs like glycine, alanine, or proline. In contrast, the CDR3 region of MM sequences presented an insertion of at least one additional charge in five out of eight cases (AL = 2/16, p = 0.039). This concerned especially sequences with a mutation at position 49M and 54S (4/5). These findings correlate with a higher percentage of glycine in AL and aspartic acid in the full-length MM sequences. Besides the IGLV segment, the first AA of the IGLJ segment also presented a high mutation frequency and exchange tendency. The AL sequences showed a mutation in seven out of sixteen cases (4x leucine) and the MM sequences in three out of eight cases (1x leucine). In the analysis of several biochemical parameters, a higher  $\beta$ -sheet aggregation tendency, Mw, and pI were detected for the MM than AL sequences.

In the analysis regarding the AL organ tropism, both subgroups displayed IGLV2-14 as the second most common IGLV subfamily. However, the AL\_H (n = 12) sequences presented more frequently an IGLJ1/IGLC1 linkage, and the AL\_HK subgroup (n = 4) an IGLJ2/IGLC2 linkage. Overall, a higher median mutation count was detected in the IGLV (9.5 vs. 7.5) and IGLJ segment of AL\_HK than AL\_H sequences. Interestingly, this difference was especially prominent in the more stable FR1 and FR3 regions. Besides these overall differences, it was possible to detect two potential associated mutations in three out of four AL\_HK sequences: at position S96T and at the seventh or eighth position in the IGLJ segment towards methionine. This might influence the overall higher percentage of serine in AL\_H sequences and threonine in AL\_HK sequences. In general, the AL\_HK sequences showed a higher Mw than the AL\_H sequences. Regarding the pI, different tendencies were found depending on considering the complete LC or only the IGLVJ segments.

The IGLV2-14-IGLJ1-IGLC1 linkage was not only found to be associated with AL and AL\_H sequences but also with a present clonal HC in serum (AL\_H HC: 37 % vs. 6 %;  $p = 0.034$ ; MM no HC n = 1). Furthermore, AL HC sequences (n = 12) showed a higher median mutation count in the IGLV and IGLJ segments, with the most prominent difference in the CDR regions. Two out of four AL no HC sequences showed a H41N mutation and one or two additional prolines in the linker region. In contrast, only one AL HC sequence showed an additional proline in the linker region. Additionally, the AL HC sequences presented a significantly higher  $\beta$ -sheet aggregation tendency (830.1 vs. 753.0,  $p = 0.018$ ), a higher pI, and a lower average Mw than the AL no HC sequences.

As already described for the HC analysis, the AL > dFLC (n = 11) subgroup also showed an association with IGLJ1/IGLC1 (MM < dFLC n = 1). Additionally, a higher mutation load in the IGLV and IGLC segment was detected in the AL > dFLC subgroup but no specific sequence feature or mutation was noted. However, the AL > dFLC sequences contained a higher percentage of several AAs including leucine (6.9 % vs. 6.4 %,  $p = 0.051$ ) and a specifically lower percentage of threonine. In addition, a higher  $\beta$ -sheet aggregation tendency and a higher Mw were detected for the AL > dFLC sequences.

### 3.5 IGLV3-1

IGLV3-1 was detected as the third most commonly used IGLV subfamily in AL and the fourth most common IGLV subfamily in MM – comprising 13 AL\_H (2x AL\_HTX), two AL\_HK, and three MM sequences (**Table 23**).

Due to the VLKL3c\_Huhn oligonucleotide binding site, only the area starting from the FR2 region was amplified and sequenced in the first PCR step. By further sequencing reactions (**Figure 10**), a N-terminal elongated sequence was generated for all AL sequences except FOR132. Therefore, this sequence was excluded in the analysis.

Also, the bulk RNA seq data of the IGLV3-1 MM sequences presented a variation compared to the other IGLV subfamilies. The generated LC sequences did not cover the complete leader region and comprised only the last five AAs. To test the comparability of the sequences, one MM sequences (MM12) was Sanger sequenced and the dominant signals were in all cases consistent with the respective sequences (**Supplementary Information Figure 14**). In addition, the bioinformatic analysis identified several sequence sections in the bulk RNA sequencing data of MM120, leading to sequence gaps and additional sequence variations in the CDR3. These gaps were resolved with the Sanger sequencing results.

Thus, with additional sequencing reactions for AL and MM samples, the LC sequence could be verified and complemented to enable detailed analysis.

### 3.5.1 Subgroup Analysis

Six out of fifteen AL IGLV3-1 patients displayed a detectable clonal HC in serum (4x IgG, 1x IgA, 1x IgG+IgD) and two out of three MM patients (2x IgG) (**Table 23**). The distribution of the HC classes is in line with the approximate percentage of the total Ig in the adult serum (Lefranc and Lefranc 2020). The third MM sequence corresponded to a patient with a dFLC >180mg/L as well as fourteen out of fifteen AL sequences. Due to the low < dFLC sample number a subgroup analysis regarding a dFLC >180 mg/L was not performed.

**Table 23. Overview of selected characteristics of 15 AL amyloidosis and 3 multiple myeloma patients with IGLV3-1 assigned light chain sequences.** The column "X AA [n]" defines how many amino acids were not determined unambiguously. Organ inv. = organ involvement, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, AL\_HTX = AL amyloidosis patients who received a heart transplant, AL = AL amyloidosis, MM = multiple myeloma, HC in IFE = detectable clonal heavy chain in the immunofixation electrophoresis in serum. NA = not available, AA = amino acid, short = no N-terminal longer sequence with additional oligonucleotides could be generated.

### 3.5.2 Mutation Frequency and Count

*To examine whether the difference in LC behavior is based on a difference in the general mutation distribution and frequency, these aspects were analyzed within the IGL segments.*

In the analysis regarding the mutational count and frequency, the IGLV3-1 MM sequences presented a higher IGLV median mutational count (12.0 vs. 7.0,  $p = 0.012$  (U-test), reference trimmed = 83 AA) and more often a mutation in the IGLC segment (33 % vs. 7 %, reference trimmed = 77 AA) than the AL sequences (**Table 24**). In more detail, a significantly higher mutational load was detected in the CDR1 (4.0 vs. 2.5,  $p = 0.032$  (U-test), reference = 12 AA) and a higher mutation frequency in the more conserved FR regions of MM sequences. As in IGLV2-14, FR1 was the least often mutated region.

In the analysis regarding the AL organ tropism, the AL\_H sequences comprised all sequences with a FR1 (50 % vs. 0 %) and IGLC mutation (8 % vs. 0 %) and showed more frequently a mutation in IGLJ, CDR2, CDR3, and less in FR2 (**Table 24**). However, it should be noted that only two sequences were assigned to the AL\_HK subgroup.

When stratifying the sequences concerning a present clonal HC, a higher mutational load was detected in the IGLV segment of AL HC (8.0 vs. 7.0) and MM HC (13.0 vs. 10.0) sequences than in the respective other subgroup (**Table 24**). While only the MM sequences with a mutation in the IGLC segment corresponded to a patient without detectable HC, all IGLC mutated AL sequences corresponded to the AL HC subgroup. In addition, AL HC sequences displayed a higher mutation frequency in FR3 than the AL no HC subgroup (100 % vs. 38 %, 2.0 vs. 2.0, reference = 32 AA). In contrast, the AL no HC sequences presented a higher mutation frequency in CDR1 (100 % vs. 67 %).

**Table 24. Comparison of the percentage of mutated IGL segments and average mutation count between AL amyloidosis and multiple myeloma IGLV3-1 assigned light chain sequences.** The analysis was also performed with respect to different subgroups. AL = AL amyloidosis patients, MM = multiple myeloma patients, CDR = complementary determining region, FR = framework region, AA = amino acid, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement. HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, \* =  $p \leq 0.05$ , Differences greater than 30 % and one (segments) or two (regions) additional mutations are marked in bold. The median mutation values were calculated using only the mutated segments/regions. The significance level was determined using the complete dataset. FOR134 was excluded due to N-terminal shortening. The Vbase2 IGLV3-1 reference sequence was used for calculations. The IGLV and the IGLC references were trimmed at the N- or C-terminus, therefore the FR1 comprised only 10 amino acids. The CDR3 region includes also the patient-specific linker region and the first two amino acids of the IGLJ segment and therefore spans 9-11 amino acids. The MM no HC subgroup comprised only one patient and was therefore neglected.

	n	IGLV 83 AA	mutated segments [%] median mutation count [n]							IGLJ 12 AA	IGLC 77 AA

### 3.5.3 Sequence Alignment

*A more detailed analysis of the LC sequences was performed on AA level to identify potential unique mutations or mutation patterns that could influence the biochemical properties of the LC itself or discriminate the subgroups. This was carried out in a step-wise procedure. First, general sequence characteristics such as mutation hotspots (mutations >50 %) and their location were identified separately for both diseases. Then the hotspots were analyzed in terms of an exchange towards a specific AA or AAs with the same side chain properties and the respective cDNA. In this analysis, the LC sequences with more than ten unambiguously determined AAs (marked as X) were included.*

Since only three MM sequences were assigned to the IGLV3-1 family, only positions that were mutated in all sequences were considered mutation hotspots. The AL sequences were still analyzed for a  $\geq 50$  % cutoff.

In a more detailed sequence analysis, it was possible to identify three AL hotspots: 32A (CDR1, 7/14), 51S (CDR2, 11/14), and 93S (CDR3, 7/14), which were all located in a CDR region and, except of 51S, shared by the MM sequences (32A = 3/3, 93S = 3/3; 51S = 2/3). The MM sequences further presented the 94S (CDR3, 3/3) mutation hotspot (**Figure 17**).

At the shared hotspot 32A, an exchange toward valine was detected in the MM sequences two times (cDNA valine = GCT→GTT), while the AL sequences presented an exchange towards valine or threonine equally frequent (3/7 each, cDNA threonine = GCT→ACT) (**Figure 17**). Position 51S (third position CDR2) can be described as the most frequently mutated AL hotspot (11/14) and in most of the cases, an exchange towards threonine was noted (6/11, cDNA = AGC→ACC). However, the MM sequences displayed a S51N exchange two times (AL = 3x). At the third shared mutation hotspot, 93S, a mutation towards asparagine was detected in three out of seven AL cases and again two times in the MM sequences. The additional MM hotspot 94S did not present a distinct exchange pattern.

Despite not reaching the mutation cutoff for both diseases, position C33 should be mentioned. If mutated, both diseases displayed exclusively an exchange towards serine (MM = 2/3, AL = 5/14, cDNA = TGC→TCC).

It is worth mentioning that the AL sequences displayed the replacement of a positive charge at position 26K (CDR1) in six out of fourteen sequences. In contrast, for two out of three MM sequences, an additional charge in the CDR2 was detected. This concerned especially position 49Q (MM120: Q49R, MM139: Q49E; AL = 1x Q49E).

Overall, the AL and MM sequences did not show a specific linker region, even though a present overlapping Ensembl reference. However, at the first AA of the IGLJ segment, a mutation was detected in more than half of the AL (8/14) and all MM sequences (3/3) (**Figure 17**). The AL sequences equally frequently showed a mutation towards glycine or alanine (3x each), which was also detected one time each in the MM sequences.

**Figure 17. Sequence sections of IGLV3-1 assigned AL amyloidosis and multiple myeloma light chain sequences.** Bold = reference sequences, underlined = CDR regions, red letter = mutation, purple highlight = mutation hotspot, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, HTX = AL amyloidosis patient who which received a heart transplant. Only one IGLC reference is shown, due to the fact, that the first amino acid can be in all cases defined as glycine. Amino acids were numbered according to the VBase2 reference. The complete amino acid sequence alignment is shown in Supplementary Information Figure 15. The complete cDNA sequence alignment is shown in Supplementary Information Figure 16.

No distinct mutation pattern was noted when analyzing the sequences concerning the AL organ tropism. In contrast, in the subgroup analysis regarding the presence of a clonal HC binding partner, several differences were detected. The 32A mutation hotspot seemed to cluster to AL no HC sequences (5/8 vs. 2/6) as well as the C33S mutation (4/8 vs. 1/6). Contrastingly, both MM HC sequences showed the C33S mutation. Both, the CDR3 region of AL HC and AL no HC sequences presented a difference in the alanine and glycine content (**Figure 18**). At position 92S and 93S, two AL HC sequences displayed a mutation towards glycine, at position 94S one time towards alanine and as already described three times at the first AA of the IGLJ segment. The AL no HC sequences showed an additional glycine in the linker region two times as well as three times at the first AA of the IGLJ segment (1x alanine).

**Figure 18.** Comparison between the amino acid probability in the CDR3 region of IGLV3-1 assigned AL amyloidosis light chain sequences in the context of the absence or presence of a clonal heavy chain in serum. AL = AL amyloidosis patients, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, blue = alanine, yellow = glycine. Amino acid numbers were assigned according to the VBase2 IGLV3-1 reference. The linker region spans positions 95 and 96, the IGLJ segments start at position 97. If only one or two amino acids were detected in the linker region, this is indicated by the width of the letter.

### 3.5.4 Amino Acid Composition

*The overall percentage of the individual AAs was calculated to evaluate the effect of the detected mutations and mutation patterns and to get an overview of the overall LC composition. Only differences  $\geq 0.5\%$  are mentioned in the following, differences  $> 0.5\%$  are numerically specified.*

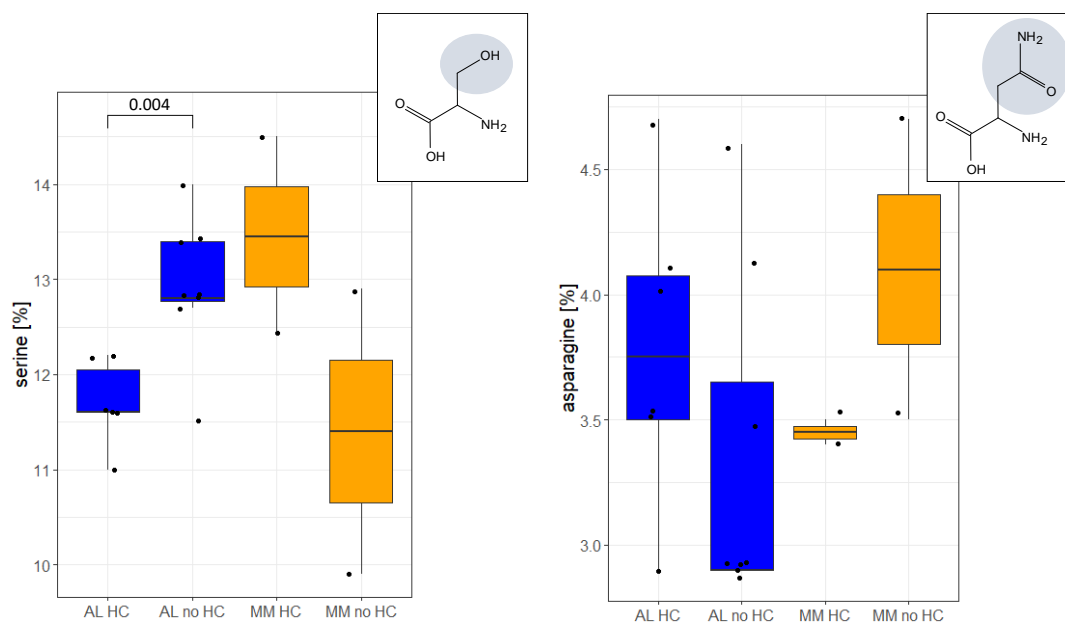

Comparing the overall AA composition of the AL and MM sequences, the only difference  $\geq 0.5\%$  was detected for the positively charged AA arginine – with a higher percentage in MM than AL sequences (1.7 % vs. 1.2 %) (**Figure 19, Supplementary Information Table 5**).

When analyzing the AL sequences with regard to the organ involvement, the AL\_H sequences presented a higher content of asparagine as well as of the small AAs alanine and proline. In contrast, the AL\_HK sequences showed an especially high percentage of serine (13.4 % vs. 12.2 %) and valine (7.9 % vs. 6.7 %) (**Figure 19**).

**Figure 19. Comparison of the overall amino acid percentage of arginine, serine, and valine in IGLV3-1 assigned AL amyloidosis and multiple myeloma light chain sequences.** (A) Comparison of the arginine percentage between IGLV3-1 assigned AL amyloidosis and multiple myeloma light chain sequences (B) Comparison of the serine and valine percentage in IGLV3-1 assigned light chain sequences between the AL organ tropism and multiple myeloma cohort. The amino acid percentage was calculated using the complete trimmed light chain sequence. AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement.

The detected potential alanine enrichment in the CDR3 region of AL HC sequences did also reflect in a higher overall alanine percentage in the complete LC (9.3 % vs. 8.7 %). In addition, the AL HC sequences presented a higher percentage of asparagine (3.8 % vs. 2.9 %) and a lower percentage of serine (11.6 % vs. 12.8 %,  $p = 0.004$  (t-test)) than the AL no HC sequences (**Figure 20**).

**Figure 20. Comparison of the overall amino acid percentage of serine and asparagine between IGLV3-1 assigned AL amyloidosis and multiple myeloma sequences with respect to the presence or absence of a clonal heavy chain.** The amino acid percentage was calculated using the complete trimmed light chain sequence. MM = multiple myeloma patients, AL = AL amyloidosis patients, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum.

### 3.5.5 Biophysical Parameters

*Several parameters were calculated to evaluate the effect of the mutations and amino acid composition on the biophysical properties of the LCs. The AGG parameter was included to determine the tendency for a beta sheet aggregation. The grand average of hydropathicity (GRAVY) value is defined by the sum of hydropathy values of all AA divided by the protein length. A negative GRAVY-value indicates a hydrophilic nature and a possible interaction of the linear protein with water molecules. The pI was also calculated to examine the theoretical stability of the LCs. In this context, the pI of the patient-derived LCs itself and the difference in comparison to a reference sequence ( $\Delta pI$ ) was calculated. This was performed for the complete LC (IGLVJC) and the IGLV and IGLJ segments (IGLVJ). In addition, the average molecular weight ( $M_w$ ) of the LCs was specified.*

The AL sequences presented a higher median AGG score than the MM sequences (1146.7 vs. 1004.0), with an especially high score in the AL\_HK sequences (1272.2; AL\_H = 1146.7) (Table 25). In addition, the AL HC sequences presented a higher score than the AL no HC subgroup (1222.2 vs. 1146.7).

No difference was noted between the AL and MM cohort with respect to the GRAVY score (Table 25). However, the AL\_H sequences presented a lower value than the AL\_HK sequences (-0.348 vs. -0.276). In the AL HC sequences, a slightly lower value than in the AL no HC sequences was detected.

Regarding the theoretical stability and solubility, the MM sequences displayed a slightly higher pI IGLVJC value (5.32 vs. 5.04) and comparable IGLVJ value (4.70 vs. 4.60) than the AL sequences; this also reflected in the  $\Delta$ pI values (IGLVJC = MM: -0.46, AL: -0.51; IGLVJ = MM: -0.15, AL: -0.38) (Table 25). Analyzing the AL organ tropism, the AL\_H sequences showed a more pronounced decrease in  $\Delta$ pI IGLVJC than the AL\_HK sequences (-0.51 vs. -0.26). When stratifying for the presence of a clonal HC, no difference was found.

The MM sequences showed a higher Mw than the AL sequences (18446 vs. 18193), with a more pronounced difference compared to the AL\_HK sequences (18156, AL\_H = 18193) (Table 25). In addition, AL HC sequences displayed a higher value than the respective other subgroup (18205 vs. 18152).

**Table 25. Overview and comparison between different biophysical parameters of IGLV3-1 assigned AL amyloidosis and multiple myeloma light chain sequences and between different subgroups.** AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, AGG =  $\beta$ -sheet aggregation tendency, GRAVY = grand average of hydropathicity, pI = isoelectric point,  $\Delta$ pI = difference between the light chain sequence and the respective reference sequence, IGLVJC = trimmed full-length light chain, IGLVJ = connected IGLV and IGLJ segments, Mw = average molecular weight. The MM no HC subgroup comprised only one patient and was therefore neglected.

	median AGG	median GRAVY	median pI IGLVJC	median $\Delta$ pI IGLVJC	median pI IGLVJ	median $\Delta$ pI IGLVJ	median Mw (average)
AL	1146.7	-0.337	5.04	-0.51	4.60	-0.38	18193
AL_H	1146.7	-0.348	5.04	-0.51	4.60	-0.38	18193
AL_HK	1272.2	-0.276	5.13	-0.26	4.78	-0.26	18156
MM	1004.0	-0.378	5.32	-0.46	4.70	-0.34	18446

AL no HC	1146.7	-0.309	5.04	-0.43	4.60	-0.45	18152
MM HC	1180.6	-0.384	5.12	-0.78	4.66	-0.39	18518

### 3.5.6 Summary IGLV3-1

IGLV3-1 seemed to be more associated with AL (third most common, 18 %, n = 15) than MM (6 %, n = 3), and also the IGLJ/IGLC linkage presented variations. While most AL cases displayed an IGLJ2/IGLC2 linkage, two out of three MM sequences showed an IGLJ1/IGLC1 linkage. Further, resolving the IGLV segment N-terminal was difficult for both diseases and in both sequencing approaches. An analysis regarding the dFLC was not performed, since IGLV3-1 was associated with AL > dFLC sequences.

In a comparison between AL and MM, the MM sequences presented more frequently mutated in the IGLV (12.0 vs. 7.0, p = 0.012) and IGLC segment – including all FR regions and especially CDR1 (4.0 vs. 2.5, p = 0.032). Both cohorts displayed three mutation hotspots, but

the MM cohort comprised only three sequences. So, only when all three sequences displayed a mutation a hotspot was defined. The MM and AL hotspots were all located in a CDR, and only one was exclusive to the AL (MM: 2/3) or MM (AL: 4/15) cohort. Despite sharing mutation hotspots, a different AA exchange tendency was noted. At position 32A, the MM sequences presented an exchange towards valine two times and the AL sequences towards valine or threonine equally. A more pronounced difference was detected for the not shared hotspot at position 51S. At this position, more than half of the AL sequences presented a S51T exchange, and two out of three MM sequences showed a S51N exchange. In addition, the CDR1 of AL sequences frequently presented the loss of a positively charged AA. In contrast, the CDR2 of MM sequences showed an additional charge. Addressing the IGLJ segment, the first AA was mutated in  $\geq 50$  % of the sequences regardless of the disease.

Comparing the overall AAs composition, the only difference  $>0.5$  % was noted for the positively charged AA arginine which was detected with a higher median percentage in the MM sequences. Regarding the pI and  $\Delta$ pI, no major differences between the two diseases were noted but the AL sequences presented a higher aggregation tendency and a lower Mw than the MM sequences.

In general, IGLV3-1 was the most common AL\_H (n = 13) IGLV subfamily. In more detail, the AL\_H subgroup comprised all sequences with a mutation in FR1 and the IGLC segment as well as a higher mutation frequency in the IGLJ segment, CDR2, and CDR3 regions. No organ-specific mutation pattern was observed but the AL\_HK (n = 2) sequences contained a notably higher percentage of serine and valine. Further, the AL\_HK sequences showed a higher aggregation tendency (AGG score) and a lower GRAVY score.

In the analysis regarding the presence of a clonal HC, the AL no HC (n = 9) subgroup displayed more frequently an IGLJ2/IGLC2 linkage than the AL HC subgroup (n = 6). However, the HC subgroups showed a higher median mutation count in the IGLV segment for both diseases. While both MM sequences with a mutation in the IGLC segment corresponded to no HC patients, all IGLC mutated AL sequences corresponded to HC patients. Despite not reaching the hotspot cutoff, the C33S mutation seemed to be important. This mutation clustered to AL no HC (4/8 vs. 1/6) and MM HC sequences (2/2 vs. 0) and might be reflected in a higher overall percentage of serine in AL no HC sequences (12.8 % vs. 11.6 %,  $p = 0.004$ ). Further, AL HC sequences showed an alanine enrichment in the CDR3 region and a higher overall percentage in the complete LC. In contrast, the AL subgroups displayed no major differences in the analysis of several biophysical parameters.

### 3.6 IGLV3-21

The IGLV3-21 subfamily was the most commonly used MM (n = 11) and the fourth most commonly used AL IGLV subfamily (n = 10). A difference was particularly noted regarding the AL organ tropism. While nine AL\_H sequences were assigned to the IGLV3-21 subfamily this was only the case for one AL\_HK sequence.

As already described for the IGLV3-1 subfamily, due to the VLKL3c\_Huhn oligonucleotide binding site only the area starting from FR2 was amplified and sequenced in the first PCR step. By further sequencing reactions, a N-terminal elongated IGLV3-21 sequence was generated in only two cases (FOR104\_H, FOR187\_HK). FOR177 exhibited multiple nucleotide signal overlaps in the FR1 and CDR1, resulting in 10 ambiguous AAs in these regions and none in the remaining sequence – therefore, it was not defined as N-terminally resolved. In addition to the difficulty resolving the N-terminus, the sequences of the IGLV3-21 subfamily showed the most abundant nucleotide overlaps in the Sanger sequencing (**Figure 21**), resulting in high numbers of ambiguous identifiable AAs in six out of ten AL cases.

**Figure 21. Section of an electropherogram of a sequencing reaction leading to one main sequence and several subsequences.** Signal overlaps of several nucleotides can be seen at several positions, some of which are marked with arrows as examples.

Contrastingly, only one MM sequence showed an additional sequence section in the bioinformatic analysis (MM138) and another one an additional sequence\_B (MM122). The additional sequence section of MM138 (sequence\_A) did not match any sequence region and was therefore neglected. To test the comparability of the sequences, three MM sequences (MM111, MM106, MM119) were also Sanger sequenced. In two cases (MM111, MM106) it was possible to generate a N-terminal elongated sequence without ambiguous AAs (**Supplementary Information Figure 17, Supplementary Information Figure 18**). Sanger sequencing of MM119 resulted in an N-terminal extended sequence but some signal overlaps were detected, resulting in not all AA positions being clearly verified (**Supplementary Information Figure 19**). However, based on the results concerning LC verification of the other IGLV subfamilies a reliable sequence can be assumed.

## 3.6.1 Subgroup Analysis

Four out of ten AL IGLV3-21 patients showed a detectable clonal HC in serum which was in all cases identified as IgG. In the MM cohort, nine out of eleven patients displayed a detectable clonal HC in serum which was identified as IgG in eight cases and once as IgA. This distribution of HC classes is in line with the approximate percentage of the total Ig in the adult serum (Lefranc and Lefranc 2020). The > dFLC subgroups comprised eight out of ten AL and only four out of eleven MM sequences (**Table 26**).

**Table 26. Overview of selected characteristics of 10 AL amyloidosis and 11 multiple myeloma patients with IGLV3-21 assigned light chain sequences.** The column "X AA [n]" defines how many amino acids were not determined unambiguously. Organ inv. = organ involvement, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement. AL = AL amyloidosis, MM = multiple myeloma, HC in IFE = detectable clonal heavy chain in the immunofixation electrophoresis in serum, AA = amino acid, NA = not available, short = no N-terminally longer sequence with additional oligonucleotides could be generated, NGS = patient samples analyzed through a next-generation sequencing approach.

**Parenthesis:** Due to the majority of AL amyloidosis sequences not being N-terminal resolved and containing a large number of ambiguously defined AAs, the sequences were not analyzed concerning mutation distribution, amino acid composition, and biophysical parameters.

Based on the results that two AL amyloidosis sequences, as well as the multiple myeloma sequences, were successfully N-terminal resolved with an additional oligonucleotide, it was assumed that the used oligonucleotide set is capable of binding at the chosen positions in FR1 and IGLC. However, most IGLV3-21 AL amyloidosis light chain sequences showed multiple nucleotide signal overlaps for a large proportion of cDNA positions – so, it can be assumed that additional subsequences are potentially present. To verify the IGLV3-21 subfamily assignment and further investigate the composition of these sequences, next-generation sequencing experiments were performed with seven AL\_H sequences (FOR117, FOR136, FOR104, FOR163, FOR169, FOR176, FOR113, **Table 26**). To be able to draw a comparison, the clearly evaluable and N-terminal resolved AL sequence was used as a positive control (FOR104\_pC). In contrast, a sequence that had been defined as non-evaluable in the overall analysis was used as negative control (FOR113\_nC). For this non-evaluable sequence, a sequence of the IGLV3-21 subfamily with 10 non-uniquely identifiable amino acids was detected in the first Sanger sequencing reaction and a sequence of the IGLV3-25 subfamily with 10 non-evaluable amino acids in the second Sanger sequencing reaction.

### 3.6.2 Verification of the AL IGLV3-21 Sequences and Subfamily Assignment through a Next-Generation Sequencing Approach

#### 3.6.2.1 Verification of AL IGLV3-21 Subfamily Assignment

In the first NGS assay, a PCR approach based on the multiplex forward oligonucleotide set (MP\_NGS\_PCR) was used to verify the IGLV3-21 family assignment and further analyze the sample composition.

In the analysis of the IGLV3-21 assigned sequences (n = 6), all samples displayed an IGLV3-21 sequence\_A and in more than half of the cases this sequence was detected in over 90 % (4/6): FOR177 = 99.5 %, FOR169 = 93.4 % and FOR176 = 93.9 % (**Table 27**). This also included the positive control sequence, which showed the highest detected percentage: FOR104\_pC = 99.9 %. In contrast, the negative control displayed an IGLV3-9 sequence\_A (3.3 %). In total, a median percentage of 93.4 % was detected in the respective sequence\_A of all seven samples.

In general, two out of six IGLV3-21 assigned samples displayed four sequences >1 % (FOR163, FOR169) (**Table 27**). In all cases, these additional sequences were assigned to the IGLV3 family – with IGLV3-21 as the most prominent subfamily. In the analysis of FOR113\_nC, a total of 16 sequences >1 % were detected, which were assigned twice to IGLV5-45, three times to IGLV3-25, and ten times to IGLV3-21. This led to the detection of IGLV3-21 as the most prominent family for this sample as well.

In conclusion, the IGLV3-21 family assignment determined in Sanger sequencing could be confirmed for all samples by the MP\_NGS\_PCR experiment. The findings also correlate with the Sanger sequencing results. Three out of four sequences without ambiguous AAs in the Sanger sequencing showed only one IGLV3-21 sequence\_A in the NGS analysis (**Table 27**). In the fourth sample FOR169, an IGLV3-21 sequence\_A was detected in 93.4 %.

**Table 27. Evaluation of the sample composition of the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples. (MP\_NGS\_PCR)** Seven AL amyloidosis samples from patients with dominant heart disease and IGLV3-21 assigned light chain sequences were examined. pC = positive control, nC = negative control, short = no N-terminally longer sequence with additional oligonucleotides could be generated, sequence\_A = sequence with the highest percentage in the next-generation sequencing analysis. The column "X AA [n]" defines how many amino acids were not determined unambiguously.

Sample	X AA [n]	Number of detected sequences >1 %	IGLV subfamily sequence_A (%)	all sequences >1 % IGLV3-21 [%]	remaining sequences >1 % IGLV3 [%]	remaining sequences >1 % not IGLV3 [%]
FOR104_pC	0	1	IGLV3-21 (99.9 %)	99.9	0	0

### 3.6.2.2 Verification of AL amyloidosis IGLV3-21 Light Chain Sequences

Additionally, it was examined whether the sequences generated by the MP\_NGS\_PCR approach were equivalent to the sequences generated by Sanger sequencing. This was demonstrated for the four sequences that showed only one IGLV sequence >1 % in the MP\_NGS\_PCR analysis (FOR136, FOR177, FOR177) – including the FOR104\_pC sample (**Figure 22, Supplementary**

**Information Figure 20).** Mismatches were only detected in and after the reverse oligonucleotide binding site. Therefore, the IGLV segments starting from CDR2 and IGLJ onwards were almost or completely covered. In conclusion, not only the family assignment but also the sequence was verified in the MP\_NGS\_PCR approach.

Verification of the Sanger sequence was also possible for FOR169 (**Supplementary Information Figure 21**). Although this sample showed in the MP\_NGS\_PCR analysis a total of four sequences >1 %, the corresponding sequence\_A was detected with 93.4 % and assigned to IGLV3-21.

For FOR163 several positions in the cDNA and AA sequence were not clearly determined by Sanger sequencing. (**Figure 23**) and in the MP\_NGS\_PCR analysis, two IGLV3-21 sequences with a comparable percentage were detected (sequence\_A = 1.43 %, sequence\_B = 1.31 %). Taken together, a deviation of the Sanger sequence to both MP\_NGS\_PCR sequences was noted at eight positions, mainly restricted to the CDR3 region (6/8).

**Figure 23. FOR163 sequence alignment of the sequence generated by Sanger sequencing and the sequence with the highest percentage in the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples.** (MP\_NGS\_PCR) Next-generation sequencing sequences were designated in descending alphabetical order based on the percentage. CDR region = underlined, IGLJ segment = blue highlight, linker region = green, sequence deviation = red, \* = matching position, VLKL3c\_huhn = IGLV3 specific forward oligonucleotide, JLHD123\_rv = IGLJ segment specific reverse oligonucleotide, Sanger = sequence generated by Sanger sequencing, NGS = sequence generated through next-generation sequencing, yellow highlight = divergent position in all three analyses, grey highlight = IUPAC code for positions with nucleotide overlaps in the sanger sequencing.

In the analysis of the FOR113\_nC sequence, ten IGLV3-21 sequences were detected in the MP\_NGS\_PCR approach. The IGLV3-21 sequence with the highest percentage (sequence\_B, 2.44 %) showed a deviation from the Sanger sequence at eleven positions. Taking all ten MP\_NGS\_PCR IGLV3-21 sequences together, a deviation to the Sanger sequence was noted at four positions. One position in the IGLJ segment can be explained by the different reverse oligonucleotides in the Sanger and NGS sequencing (**Figure 24**)

It is of note that these two samples shared one remarkable position in FR3: at this position, the Sanger sequences of FOR113\_nC and FOR163 displayed an adenine, while all detected NGS sequences showed a guanine, which is in accordance with the IGLV3-21 reference (**Figure 23, Figure 24**). An adenine would lead to an exchange on AA level at position 80 from glycine towards the negatively charged AA glutamic acid.

**Figure 24.** FOR113 sequence alignment of the sequence generated by Sanger sequencing and the sequence with the highest percentage in the IGLV3-21 next-generation sequencing experiment based on multiplex oligonucleotide PCR samples. (MP\_NGS\_PCR) Next-generation sequencing sequences were designated in descending alphabetical order based on the percentage. CDR region = underlined, IGLJ segment = blue highlight, linker region = green, sequence deviation = red, \* = matching position, VLKL3c\_huhn = IGLV3 specific forward oligonucleotide, JLHD123\_rv = IGLJ segment specific reverse oligonucleotide, Sanger = sequence generated by Sanger sequencing, NGS = sequence generated through next-generation sequencing, yellow highlight = divergent position in all three analyses, grey highlight = IUPAC code for positions with nucleotide overlaps in the sanger sequencing.

Taken together, a clear verification of the Sanger sequence was possible in five cases, including the positive control. The two remaining sequences share a deviation in the FR3 between the Sanger and MP\_NGS\_PCR approach. Additionally, FOR163 showed a total of eight and the negative control sequence four divergences between all IGLV3-21-assigned MP\_NGS\_PCR sequences and the respective Sanger sequence.

### 3.6.3 Analysis for Lack of N-terminal Coverage of IGLV3-21 AL Sequences through a Next-Generation Sequencing Approach

#### 3.6.3.1 Analysis of the IGLV3-21 Sample Composition and Comparison to the MP<sub>NGS\_PCR</sub> Approach

In a second approach, PCR samples that should generate IGLV3 N-terminally longer sequences were analyzed using NGS (N<sub>NGS\_PCR</sub>).

Interestingly, the N<sub>NGS\_PCR</sub> samples contained a higher median number of sequences >1 % than the MP<sub>NGS\_PCR</sub> samples (14 vs. 1;  $p = 0.038$  (U-test), **Table 28**). While in the MP<sub>NGS\_PCR</sub> approach four sequences displayed only one sequence >1 %, this was exclusivity detected for the N<sub>NGS\_PCR</sub> FOR104\_pC sequence. However, the FOR113\_nC sample displayed the second least number of sequences  $\geq 1$  % ( $n = 5$ ). Furthermore, a lower overall median percentage of all sequence\_A compared to the MP<sub>NGS\_PCR</sub> samples was detected (18.4 % vs. 93.4 %). Additionally, while in the MP<sub>NGS\_PCR</sub> approach, all AL samples displayed an IGLV3-21 sequence\_A, this was only the case for two samples in the N<sub>NGS\_PCR</sub> analysis (FOR177, FOR104\_pC).

However, the positive control sequence FOR104\_pC showed an IGLV3-21 sequence\_A with an abundance of 99.91 %. The negative control sequence FOR113\_nC showed an IGLV3-25 sequence\_A with 55.15 % as well as two additional IGLV3-25 sequences (sequence\_B = 17.47 %, sequence\_C = 6.42 %). Thus, for these two samples, the IGLV family assignment based on the Sanger sequencing and the N<sub>NGS\_PCR</sub> approach was consistent.

FOR177 displayed 20 different sequences with an abundance >1 % but only sequence\_A was assigned to the IGLV3-21 subfamily (16.51 %). Based on these 20 sequences, IGLV3-27 was the most prominent IGLV3 subfamily (6x, 28.99 %). IGLV3-27 was also the most prominent IGLV3 subfamily in FOR176 (8x, 49.61 %, sequence\_A = IGLV3-10 17.77 %), with a total of 14 sequences >1 % including one IGLV3-21 sequence (sequence\_F = 6.07 %). The remaining samples FOR136 (32.5 %), FOR163 (50.04 %), and FOR169 (66.24 %) displayed IGLV3-25 as the most abundant IGLV3 subfamily. None of these three samples contained an IGLV3-21 sequence in a total of 23 (FOR136), 17 (FOR163), or nine (FOR169) sequences  $\geq 1$  %. FOR163 and FOR169 displayed an IGLV3-25 sequence\_A (FOR163 = 18.36 %, FOR169 = 33.26 %) and FOR136 a sequence which was not ambiguously assigned to IGLV3-25 or IGLV3-16 (13.20 %).

Based on the detected IGLV subfamily distribution, it should be mentioned that the standard multiplex approach has been shown to bind on IGLV3-25 (FOR111). In general, both the

VLKL3c\_huhn (20 nucleotides) and VLKL3\_A\_fw\_NB (19 nucleotides) oligonucleotides show no mismatch to the IGLV2-25\*03 and IGLV3-25\*03 reference sequences. Regarding IGLV3-27: the VLKL3c\_Huhn oligonucleotide shows only one (3<sup>rd</sup> position: A vs. T) and the VLKL3\_A\_fw\_NB oligonucleotide none mismatch to the IGLV3-27 reference sequence. Therefore, the amplification of these IGLV subfamilies should also be ensured in the first MP\_NGS\_PCR approach.

**Table 28. Evaluation of the sample composition of the IGLV3-21 next-generation sequencing experiment based on an IGLV3-specific forward oligonucleotide.** (N\_NGS\_PCR)

Seven AL amyloidosis samples from patients with dominant heart disease and IGLV3-21 assigned light chain sequences were examined. pC = positive control, nC = negative control, short = no N-terminally longer sequence with additional oligonucleotides could be generated, sequence\_A = sequence with the highest percentage in the next-generation sequencing analysis. The column "X AA [n]" defines how many amino acids were not determined unambiguously.

Sample	Number of detected sequences >1 %	IGLV subfamily sequence_A (%)	Number of IGLV3-21 sequences > 1 %	all sequences >1 % IGLV3-21 [%]	Most prominent IGLV3 subfamily (%)
FOR104_pC	1	IGLV3-21 (99.91)	1	99.9	IGLV3-21 (99.91 %)
FOR136	23	IGLV3-16/IGLV3-25 (13.20)	0	0	IGLV3-25 (32.25 %)
FOR163	17	IGLV3-25 (18.36)	0	0	IGLV3-25 (50.04 %)
FOR169	9	IGLV3-25 (33.26)	0	0	IGLV3-25 (66.24 %)
FOR176	14	IGLV3-10 (17.77)	1	6.1	IGLV3-27 (49.61 %)
FOR177	20	IGLV3-21 (16.51)	1	16.5	IGLV3-27 (28.99 %)
FOR113_nC	6	IGLV3-25 (55.15)	0	0	IGLV3-25 (79.04 %)

### 3.6.3.2 Sequence Analysis and Comparison to the MP\_NGS\_PCR Approach

In the analysis of the three samples comprising an IGLV3-21 sequence in both the MP\_NGS\_PCR and N\_NGS\_PCR approach, a sequence match was found – including the positive control sample FOR104\_pC (**Figure 25**).

**Figure 25. Sequence alignment of the IGLV3-21 sequence with the highest percentage in the MP\_NGS\_PCR approach and the IGLV3-21 sequences in the N\_NGS\_PCR approach. (A) sequence alignment positive control FOR104\_pC (B) sequence alignment FOR176 (C) sequence alignment FOR136 (D) sequence alignment FOR177. CDR region = underlined, IGLJ segment = blue highlight, linker region = green, sequence deviation = red, \* = matching position, VLKL3c\_huhn = IGLV3 specific forward oligonucleotide, JLHD123\_rv = IGLJ segment specific reverse oligonucleotide, Sanger = sequence generated by Sanger sequencing, NGS = sequence with the highest percentage in the next-generation sequencing experiment, next-generation sequencing sequences were designated in descending alphabetical order based on the percentage.**

In the remaining four cases (including FOR113\_nC), no IGLV3-21 sequence was detected in the N\_NGS\_PCR approach. To exclude the possibility of erroneous assignment, the sequence\_A was compared between the two approaches. In the analysis of FOR136, 43 deviations in a total of 171 overlapping nucleotides were detected between the respective sequence\_A sequences. Similar ratios were detected in FOR163 (43 deviations, 168 overlapping nucleotides) and FOR169 (47 deviations, 178 overlapping nucleotides) (**Supplementary Information Figure 22**).

In the next step, it was evaluated if the sequence\_A of the N\_NGS\_PCR approach was also present in the MP\_NGS\_PCR approach (**Supplementary Information Figure 23**). This analysis could not be performed for FOR136, because only one sequence was detected in the MP\_NGS\_PCR approach (IGLV3-21). In the analysis of the N\_NGS\_PCR FOR163 sample, an IGLV3-25 sequence\_A was detected and, in the MP\_NGS\_PCR approach sequence\_D was assigned to this subfamily. However, the sequences showed several deviations (22 in 178 overlapping nucleotides). This was also observed for FOR169; the N\_NGS\_PCR sequence A was assigned to the IGLV3-25 subfamily as well as the MP\_NGS\_PCR sequence\_B, sequence\_C, and sequence\_D. Sequence\_D showed the highest sequence similarity with nine deviations (172 overlapping nucleotides).

In the analysis of the negative control sample FOR113\_nC, N\_NGS\_PCR sequence\_A, \_B, and \_C, as well as the MP\_NGS\_PCR sequence\_C, \_D, and \_N, were assigned to the IGLV3-25 subfamily. No concordance could be found between the sequences of both approaches. When comparing the N\_NGS\_PCR IGLV3-25 sequence with the Sanger sequencing result, no overall matching sequence was found. However, taking all three sequences into account, no position showed a deviation in all three sequences – except one, which can be explained by the reverse oligonucleotide binding site.

Taken together, the results concerning the FOR104\_pC as well as the FOR113\_nC N\_NGS\_PCR samples match the Sanger sequencing results. In two additional samples, the IGLV3-21 sequence\_A of the MP\_NGS\_PCR approach is in accordance with a detected N\_NGS\_PCR IGLV3-21 sequence. In the remaining three cases no IGLV3-21 sequence was detected in the N\_NGS\_PCR approach and in two cases the respective sequence\_A showed several deviations from sequences of the same IGLV subfamily in the MP\_NGS\_PCR approach.

#### 3.6.4 Sequence Alignment

*A more detailed analysis of the LC sequences was performed on AA level to identify potential unique mutations or mutation patterns that could influence the biochemical properties of the LC itself or discriminate the subgroups. This was carried out in a step-wise procedure. First, general sequence characteristics such as mutation hotspots (mutations >50 %) and their location were identified separately for both diseases. Then the hotspots were analyzed in terms of an exchange towards a specific AA or AAs with the same side chain properties and the respective cDNA. In this analysis, the LC sequences with more than ten unambiguously determined AAs (marked as X) were included.*

When analyzing the sequences in more detail, it was noticed that there seem to be specific positions – especially in the FR regions – that are particularly characterized by nucleotide signal overlaps: 38K (FR2, 3/10 X), 44V (FR2, 3/10 X), 63G (FR3, 3/10 X), 68N (FR3, 3/10 X), 72L

(FR3, 3/10 X), 83A (FR3, 3/10 X), 87C (FR3, 3/10 X) and 89V (CDR3, 3/10 X) and most prominent 84D (FR3, 4/10 X) (**Figure 26 A**).

The AL and MM sequences each showed only one mutation hotspot in the IGLV segment, which was also exclusive to the disease (**Figure 26 A**). For the AL hotspot 92S (6/10, 1x X, CDR3), a most prominent exchange from serine towards threonine (3/6, cDNA = AGT→ACT) was noted. The MM sequences presented a 92S mutation only twice (1x G, 1x F). The MM hotspot was also located in the CDR3 region (93S) and a mutation was detected in seven out of eleven cases (AL = 4/10) with a most prominent exchange towards a charged AA (2x R, 1x D, AL = 0).

Besides these two hotspots, two additional positions with a directed exchange pattern should be mentioned. A G80E (FR3) mutation was detected in four AL sequences (MM = 0x) but this position could not be verified in the comparison between the Sanger sequencing and MP\_NGS\_PCR approach. In contrast, the MM sequences showed a Y86F mutation in four cases (1x H, FR3) and none of the AL sequences.

Overall, an additional charge in the CDR3 region was detected in five MM cases and only once in the AL cohort (**Figure 26 B**). In this context, the IGLV-IGLJ linker region was not considered, based on the fact that a similar linker region was detected for both diseases. In general, the Ensembl IGLV3-21 reference showed four additional AAs (DHPT) at the C-terminus than the Vbase2 reference sequences. However, most of the AL and MM sequences showed only two AAs in the linker region, and in more than half of the cases, they were identified as aspartic acid and histidine.

A mutation hotspot for both diseases was also defined at the first position of the IGLJ segment (AL = 5/10, 2x X, MM = 7/11). The MM sequences showed a mutation towards the small AAs proline or glycine in two cases each – this was not detected in the AL cohort.

A

B

**Figure 26. Sequence sections of IGLV3-21 assigned AL amyloidosis and multiple myeloma light chain sequences.** A) Sequence sections of IGLV3-21 assigned AL amyloidosis and multiple myeloma light chain sequences B) CDR3 region of IGLV3-21 AL amyloidosis and multiple myeloma sequences with respect to additional charges C) Sequence sections of IGLV3-21 AL amyloidosis sequences stratified for the presence or absence of a clonal heavy chain in serum. Bold = reference sequences, underlined = CDR regions, red highlight = discrepancy between the VBase2 and Ensembl IGLV3-21 reference, red letter = mutation, purple highlight = mutation hotspot, blue highlight = interesting mutation, green highlight = additional positive charge, light red highlight = additional negative charge, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patients, AL = AL amyloidosis patients, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum. Only one IGLC reference is shown because the first amino acid can be defined as glycine in all cases. Amino acids were numbered according to the VBase2 reference. The complete amino acid sequence alignment is shown in Supplementary Information Figure 24. The complete cDNA sequence alignment is shown in Supplementary Information Figure 25.

Interestingly, the sequences with ambiguous AA positions were mostly assigned to the AL HC group (3/4 vs. 2/6). In addition, the AL hotspot at position 92S was enriched in AL no HC sequences (5/6 vs. 1/4) as well as a mutation at the first position of the IGLJ segment (4/6 vs. 1/4, 1x X AL no HC) (**Figure 27**). No specific mutation pattern or sequence characteristics were noted when stratifying for a dFLC >180 mg/L.

**Figure 27. Sequence sections of IGLV3-21 AL amyloidosis sequences stratified for the presence or absence of a clonal heavy chain in serum.** Bold = reference sequences, underlined = CDR regions, red highlight = discrepancy between the VBase2 and Ensembl IGLV3-21 reference, red letter = mutation, light blue highlight = mutation hotspot, dark blue highlight = interesting mutation, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patients, AL = AL amyloidosis patients, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum. Amino acids were numbered according to the VBase2 reference. The complete amino acid sequence alignment is shown in Supplementary Information Figure 24. The complete cDNA sequence alignment is shown in Supplementary Information Figure 25.

### 3.6.5 Summary IGLV3-21

IGLV3-21 was the most common MM IGLV subfamily (21 %, n = 11; AL = 13 %, n = 10) and was found more frequently in AL\_H than AL\_HK sequences (15 % vs. 5 %). In addition, an association with MM\_HC and MM < dFLC was detected. Also, the IGLV-IGLJ-IGLC connection differed between the two diseases. While most of the MM sequences displayed an IGLJ2/IGL2 linkage, the AL sequences showed an IGLJ2/IGLC2 or IGLJ3/IGLC3 linkage equally frequently. In addition, AL HC sequences showed mostly an IGLJ2/IGLC2 connection, and AL no HC sequences an IGLJ3/IGLC3 connection.

Several difficulties occurred in the sequencing of the IGLV segment of the AL sequences: In the majority of the cases, it was not possible to resolve the N-terminus (FR1-CDR1) of the IGLV segment. Further, IGLV3-21 presented as the IGLV subfamily with the most abundant and highest number of ambiguous identifiable AAs. Only four of eleven AL sequences did not show nucleotide signal overlaps resulting in undeterminable AAs. Based on these characteristics, an evaluation regarding the mutation distribution, AA composition, and biophysical parameters was assumed to not be reasonable.

In the next step, NGS experiments were conducted with seven AL sequences to verify the IGLV3-21 subfamily assignment and further investigate the composition of these sequences/samples. These seven samples included an evaluable N-terminal resolved sequence

as the positive control and as the negative control a sequence that was defined as non-evaluable (IGLV3-21 in the first PCR reaction and IGLV3-25 in the second PCR reaction).

At first, NGS was used to analyze a PCR approach based on a multiplex oligonucleotide set (MP<sub>NGS\_PCR</sub>). It was possible to detect an IGLV3-21 sequence with the highest percentage for each IGLV3-21 assigned sample (median sequence A: 93.4 %). The negative control sample showed an IGLV3-9 sequence with the highest percentage (3.3 %), but considering all sequences  $\geq 1$  %, IGLV3-21 was the most prominent IGLV subfamily. Four samples, including the positive control, showed only one sequence with a percentage  $\geq 1$  % and in a comparison with the Sanger sequencing results, the sequences matched (CDR2-IGLJ). Two samples displayed four sequences  $\geq 1$  %; in one sample the NGS and Sanger sequencing matched (sequence\_A: 93.4 % IGLV3-21). In the second case seven mismatches, mainly restricted to the CDR3 region, were noted (sequence\_A: 1.4 % IGLV3-21). The negative control showed 16 sequences with a percentage  $\geq 1$  %. Evaluating these 16 sequences together, four positions showed a deviation from the Sanger sequence. Thus, the IGLV subfamily assignment was verified in all cases and in the majority of the cases also the sequence itself. In the remaining samples, the sequences were verified for over 90 % of the positions.

In the next step, NGS was used to analyze PCR samples that should generate IGLV3 N-terminally elongated sequences. Interestingly, these N<sub>NGS\_PCR</sub> samples contained a higher amount of sequence  $\geq 1$  % (14 vs. 1;  $p = 0.038$ ) and a lower percentage of the respective sequence\_A (18.4 % vs. 93.4 %) compared to the MP<sub>NGS\_PCR</sub> approach. However, only three samples showed an IGLV3-21 sequence  $\geq 1$  %. Here, the IGLV3-21 sequence was detected with the highest percentage in two sequences, including the positive control. In all three cases, the IGLV3-21 N<sub>NGS\_PCR</sub> sequence matched the MP<sub>NGS\_PCR</sub> IGLV3-21 sequence\_A. It is worth mentioning that for the negative control, the sequence with the highest percentage was identified as IGLV3-25, which matched the Sanger sequencing assignment. Taking all three N<sub>NGS\_PCR</sub> IGLV3-25 sequences into account, no position showed a deviation in all three sequences. So, for the positive and negative control it was possible to generate expected results but beyond that no new information could be gained.

In a next step, the complete AL and MM cohorts were analyzed concerning their mutation hotspots. Here, it was noticeable that the AL (92S) and MM (93S) hotspots were both located in the CDR3 but did not concern the same position. In addition, two positions showed a direct exchange pattern: G80E (AL) and Y86F (MM), but the NGS experiments could not verify the G80E mutation. As already described for the other IGLV subfamilies, it was possible to identify different patterns in the context of charged and small AAs. While the CDR3 region of MM

sequences displayed an additional charge in five out of eleven cases, this was only noted once in the AL cohort. Even though the first AA of the IGLJ segment presented as a mutation hotspot in both cohorts, an exchange towards a small AA was detected in more than half of the cases in the MM sequences and none of the AL sequences. It should also be mentioned that the AL sequences with many ambiguous AA positions belonged to the AL\_HC group (4/5 vs. 2/6).

### 3.7 IGLV6-57 and IGLV2-23

Concerning the IGLV subfamily usage, a significant difference between the two diseases was especially detected for IGLV6-57 and IGLV2-23. IGLV6-57 was found to be the most used AL IGLV subfamily (n = 18) and was only detected once in the MM cohort. In addition, IGLV6-57 presented as the most used AL\_HK subfamily and was detected with a more than two times higher percentage than in the AL\_H subgroup. However, half of the AL\_HTX sequences corresponded to this subfamily (4/8). In contrast, eight MM samples and no AL samples were assigned to the IGLV2-23 subfamily. This is of particular interest due to IGLV2-23 being detected as one of the third most commonly used MM IGLV subfamilies (together with IGLV2-14). Based on this prominent difference and the assumed divergent amyloidogenic potential, a comparison between these two IGLV subfamilies was performed.

The AL IGLV6-57 sequence FOR133 was not used for further analysis due to fourteen not clearly determined AAs. In addition, since only one MM sequence was assigned to the IGLV6-57 subfamily this sequence was also neglected in the evaluation (MM112) – however, it was possible to verify the sequence by Sanger sequencing (**Supplementary Information Figure 26**).

In the bioinformatic analysis of the IGLV2-23 MM sequences MM107 and MM132, it was possible to detect an additional sequence segment. In the case of MM107, this sequence section was not clearly assigned to a specific region but showed partial matches with the IGLC segment (**Supplementary Information Figure 27**). Regarding MM132, the additional sequence section was an exact copy of an IGLC region and was therefore not investigated further (**Supplementary Information Figure 28**).

#### 3.7.1 Subgroup Analysis

More than half of the AL IGLV6-57 sequences corresponded to patients with detectable HC (11/17, 6x IgG, 4x IgA, 1x IgD, 1x NA) and nine to patients with a dFLC >180 mg/L (**Table 29**). Since most IGLV6-57 AL\_HK sequences corresponded to a patient with detectable HC (7/8), the respective analysis was performed using only the IGLV6-57 AL\_H sequences.

Seven out of eight IGLV2-23 MM patients showed a detectable clonal HC (5x IgG, 2x IgA), and six patients a dFLC >180 mg/L. Therefore, a comparison between these subgroups was not performed.

As a side note, the distribution of HC classes is in line with the approximate percentage of the total Ig in the adult serum for both diseases (Lefranc and Lefranc 2020).

**Table 29. Overview of selected characteristics of 18 AL amyloidosis patients and one multiple myeloma patient with IGLV6-57 assigned light chain sequences and 8 multiple myeloma patients with IGLV2-23 assigned light chain sequences.** The column "X AA [n]" defines how many amino acids were not determined unambiguously. Organ inv. = organ involvement, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, AL\_HTX = AL amyloidosis patients who received a heart transplant, AA = amino acid, AL = AL amyloidosis, MM = multiple myeloma, HC in IFE = detectable clonal heavy chain in the immunofixation electrophoresis in serum, NA = not available.

Starting with the overall LC composition, the AL IGLV6-57-IGLJ-IGLC linkage has already been described in chapter 3.3.2 and a most prominent linkage with IGLJ2/IGLC2 was detected

(**Table 19**). Three IGLV2-23 MM sequences displayed an IGLJ3/IGLC3 linkage, two an IGLJ2/IGLC2 linkage, and in three cases the IGLJ segment was not determined unambiguously between IGLJ2 and IGLJ3.

### 3.7.2 Mutation Frequency and Count

*To examine whether the difference in LC behavior is based on a difference in the general mutation distribution and frequency, these aspects were analyzed within the IGL segments.*

Comparing the AL IGLV6-57 and IGLV2-23 MM sequences, it must be considered that the IGLV segment of the IGLV6-57 sequences was trimmed and the FR1, as well as the first AA of the CDR1 region, were missing. In the following, only the adjusted IGLV2-23 sequences were considered. However, with respect to the analyzed section, the IGLV6-57 reference comprises one additional AA (CDR1-CDR3, IGLV6-57 = 75 AA, IGLV2-23 = 74 AA). Besides, the FR1 of IGLV2-23 MM sequences showed a mutation in 38 % of the cases and, if mutated, a median mutation count of 1.0.

Overall, the IGLV2-23 MM sequences displayed a mutational load almost twice as high as the IGLV6-57 AL sequences (11.5 vs. 6.0,  $p = 1.60e-06$  (t-test)) (**Table 30**). However, not only a higher overall mutation count but also a higher mutation frequency and mutation count was detected in all regions, except CDR3. The most prominent differences were noted in CDR1 (3.5 vs. 1.0,  $p = 0.003$  (t-test), IGLV6-57 = 12 AA, IGLV2-23 = 13 AA), CDR2 (88 % vs. 53 %,  $p = 0.027$  (U-test), both references = 7 AA) and FR3 (100 % vs. 65 %,  $p = 0.023$  (U-test), IGLV6-57 = 34 AA, IGLV2-23 = 32 AA). Additionally, a more frequently mutated IGLJ segment was detected in the MM IGLV2-23 sequences (75 % vs. 53 %, reference = 12 AA).

When stratifying the IGLV6-57 sequences for the AL organ tropism, the AL\_H sequences (IGLV = 7.0, IGLJ = 78 %, IGLC = 22 %, reference = 74 AA) and especially the AL\_HTX sequences (IGLV = 7.5, IGLJ = 75 %, IGLC = 25 %) showed a higher mutational load or frequency than the AL\_HK sequences in all segments (IGLV = 5.0, IGLJ = 25 %, IGLC = 0 %)(**Table 30**). In addition, a higher mutation frequency was detected in the FR3 of AL\_H sequences compared to AL\_HK sequences (100 % vs. 25 %,  $p = 0.007$  (t-test), reference = 34 AA).

In the analysis of IGLV6-57 AL\_H sequences regarding a potential HC binding partner, the AL\_H HC sequences presented less frequently mutated than the AL\_H no HC sequences in the IGLV (6.5 vs. 7.5), IGLJ (50 % vs. 100 %) and IGLC segment (0 % vs. 50 %) (**Table 30**). This difference was also noted for CDR2 (25 % vs. 75 %).

When stratifying for a dFLC >180 mg/L, the IGLV6-57 AL < dFLC sequences showed, if mutated, more mutations in the IGLJ segment (2.0 vs. 1.0). Despite no overall detected difference in the IGLV segment, the FR3 showed more mutations in the AL > dFLC subgroup (1.0 vs. 2.5) (**Table 30**).

**Table 30. Comparison of the percentage of mutated IGL segments and the average mutation count between the IGLV6-57 assigned AL amyloidosis and IGLV2-23 assigned multiple myeloma light chain sequences.** The analysis was also performed with respect to different subgroups. The IGLV6-57 MM light chain sequence is not shown. AA = amino acid, CDR = complementary determining region, FR = framework region, AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AA = amino acid, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement. HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L, \* = p ≤0.05, differences greater than 30 % and one (segments) or two (regions) additional mutations are marked in bold. The median mutation values were calculated using only the mutated segments/regions. The significance level was determined using the complete dataset. FOR133 was excluded due to several not unambiguously defined amino acids. The median mutation values were calculated using only the mutated segments/regions. The Vbase2 reference sequences were used for calculations, the IGLC reference was trimmed at the C-terminus. The CDR3 region also includes the patient-specific linker region and the first two amino acids of the IGLJ segment. It, therefore, spans 9-11 amino acids in the IGLV6-57 subgroup and 8-11 amino acids in IGLV2-23.

				mutated segments [%] median mutation count [n]

### 3.7.3 Sequence Alignment

*A more detailed analysis of the LC sequences was performed on AA level to identify potential unique mutations or mutation patterns that could influence the biochemical properties of the LC itself or discriminate the subgroups. This was carried out in a step-wise procedure. First, general sequence characteristics such as mutation hotspots (mutations >50 %) and their location were identified separately for both diseases. Then the hotspots were analyzed in terms of an exchange towards a specific AA or AAs with the same side chain properties and the respective cDNA. In this analysis, the LC sequences with more than ten unambiguously determined AAs (marked as X) were included.*

When analyzing the IGLV6-57 sequences in more detail, it is noticeable that only one position in the CDR3 region is mutated in over 50 % of the AL sequences (97S), including four out of eight AL\_HK and six out of nine AL\_H sequences (**Figure 28 A**). When considering the organ involvement separately, three hotspots were additionally defined for the AL\_HK sequences: 53N (3<sup>rd</sup> position CDR2, 4/8), 96S (CDR3, 5/8), and 98N (CDR3, 4/8). While at position 53N an exchange towards a charged AA was noted in three out of four AL\_HK cases, no directed exchange pattern was observed for the other two hotspots. In contrast, two additional AL\_H hotspots were identified, and both showed a specific exchange pattern. At position 69S (FR3), four out of nine AL\_H sequences displayed an exchange towards the positively charged AA arginine (1x X with R as a possibility, cDNA = AGC→AGG or AGA). At position 82 (FR3), an exchange from the positively charged AA lysine towards glutamine was detected four times and one time towards threonine (cDNA glutamine = AAG→CAG).

Overall, no consistent pattern was noted in the AL IGLV6-57 IGLV-IGLJ linker region.

When stratifying the AL\_H sequences for the absence or presence of a clonal HC, it is noticeable that an exchange towards phenylalanine was detected in three out of four AL\_H HC sequences at position 50Y and at position 37Y twice. Remarkably, the two Y50F and Y37F mutated sequences corresponded to AL\_HTX patients. All Y50F mutated sequences also cluster to the > dFLC subgroup (cDNA Y50F = TAT→TTT).

Regarding the IGLV2-23 MM sequences, eight positions – mainly restricted to the CDR regions – were identified as mutation hotspots: 29V (CDR1, 4/8), 31S (CDR1, 5/8), 32Y (CDR1, 4/8), 49M (FR2, 4/8), 53G (CDR2, 6/8), 54S (3<sup>rd</sup> position CDR2, 5/8), 96S (CDR3, 5/8) and 97S (CDR3, 7/8) (**Figure 28 B**). However, only at two positions, a distinct exchange was noted: V29I = 3/4 (cDNA = GTT→ATT) and G53V = 4/6 (cDNA = GGC→GTC). Also, in three out of eight cases, an exclusive exchange towards asparagine was noted at position 26S. Although there is no overlapping reference, the linker region contained only a threonine in six cases (1x TS, 1x nothing).

**Figure 28. Sequence sections of IGLV6-57 assigned AL amyloidosis and multiple myeloma light chain sequences and IGLV2-23 assigned multiple myeloma light chain sequences. (A) Sequence section of IGLV6-57 assigned AL amyloidosis and multiple myeloma light chain sequences. (B) Sequence section of IGLV2-23 assigned multiple myeloma light chain sequences. Bold = reference sequences, underlined = CDR regions, red letter = mutation, purple highlight = mutation hotspot, blue highlight = interesting mutation, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant. Only one IGLC reference is shown because the first amino acid can be in all cases defined as glycine. Amino acids were numbered according to the VBase2 reference. The complete IGLV6-57 amino acid sequence alignment is shown in Supplementary Information Figure 29. The complete IGLV6-57 cDNA sequence alignment is shown in Supplementary Information Figure 30. The complete IGLV2-23 sequence amino acid alignment is shown in Supplementary Information Figure 31. The complete IGLV2-23 sequence cDNA alignment is shown in Supplementary Information Figure 32.**

In a comparison between AL IGLV6-57 and MM IGLV2-23, the MM IGLV2-23 sequences presented more mutation hotspots (1 vs. 8) and the two cohorts share mutation hotspots at the third position of the CDR2 (AL\_HK) and at the two last positions in the IGLV segment (one only AL\_HK). Moreover, mutations in the IGLJ segment as well as the first AA of the IGLC segment were detected in both subgroups with the same AA exchanges.

As already observed for the other IGLV subfamilies, the IGLV6-57 sequences presented charge changes in specific regions as well (Figure 29). More than half of the AL IGLV6-57 sequences presented an additional charge in the CDR1 (10/18) and interestingly, a certain organ tropism

was noted. While five AL\_H sequences presented an exchange towards the negatively charged AA aspartic acid (1x histidine), four AL\_HK sequences presented an additional positive charge (3x arginine, 1x lysine,  $p = 0.036$  (Chi)). Also, the CDR2 region showed an insertion of an additional charge in eight AL IGLV6-57 sequences, which clustered to the < dFLC subgroup (6/9 vs. 2/9). In contrast, the CDR3 region displayed an enrichment of charged AAs especially prominent in AL\_HK sequences (6/8, AL\_H  $n = 1$ ;  $p = 0.012$  (Fischer)). Regarding the IGLV2-23 MM sequences, an accumulation of additional charges was only noted in the CDR3 region (4/8, CDR1 1/8, CDR2 1/8).

**Figure 29. Sequence section of IGLV6-57 assigned AL amyloidosis and multiple myeloma light chain sequences and IGLV2-23 assigned multiple myeloma light chain sequences with respect to additional charges.** (A) Sequence section of IGLV6-57 assigned AL amyloidosis and multiple myeloma light chain sequences. (B) Sequence section of IGLV2-23 assigned multiple myeloma light chain sequences. Bold = reference sequences, underlined = CDR regions, red letter = mutation, light red highlight = additional negative charge in a CDR region, green highlight = additional positive charge in a CDR region, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant. Only one IGLC reference is shown because the first AA can in all cases be defined as glycine. Amino acids were numbered according to the VBase2 reference. The complete IGLV6-57 amino acid sequence alignment is shown in Supplementary Information Figure 29. The complete IGLV6-57 cDNA sequence alignment is shown in Supplementary Information Figure 30. The complete IGLV2-23 sequence amino acid alignment is shown in Supplementary Information Figure 31. The complete IGLV2-23 sequence cDNA alignment is shown in Supplementary Information Figure 32.

### 3.7.4 Amino Acid Composition

*The overall percentage of the individual AAs was calculated to evaluate the effect of the detected mutations and mutation patterns and to get an overview of the overall LC composition. Only differences  $\geq 0.5\%$  are mentioned in the following, differences  $>0.5\%$  are numerically specified.*

To achieve comparability between IGLV6-57 and IGLV2-23, the median AA percentage of the respective full-length reference sequences, without patient-specific linker region, was also calculated. Considering the reference VBase2 IGLV segment individually, it is striking that there is almost no commonality between these subfamilies. The IGLV6-57 reference contains an especially lower amount of alanine (3.1 % vs. 7.2 %) and glycine (6.1 % vs. 11.3 %) as well as a higher amount of aspartic acid (6.1 % vs. 3.1 %) than the IGLV2-23 reference. Overall, the IGLV6-57 reference comprises a higher number of negatively charged AAs (10 vs. 6). Also, differences regarding the positively charged AAs were noted; the IGLV2-23 reference sequence contained a lower amount of arginine (2.1 % vs. 4.0 %) and a higher amount of lysine (4.1 vs. 2.0).

In the IGLV6-57 AL as well as IGLV2-23 MM LC sequences no difference ( $\geq 0.5\%$ ) was detected for the AAs cysteine, glutamine, glutamic acid, glycine, leucine, methionine, proline, and tryptophan for the full-length reference sequences (**Supplementary Information Table 6, Supplementary Information Table 7**). In contrast, in both the IGLV2-23 MM sequences and the IGLV6-57 AL, an increase in aspartic acid (AL = 4.8 % vs. 5.5 %, MM = 2.7 % vs. 3.3 %), isoleucine (AL = 3.0 % vs. 3.6 %, MM = 2.7 % vs. 3.3 %), phenylalanine (AL = 2.4 % vs. 3.0 %, MM = 2.2 % vs. 2.7 %) and threonine (AL = 7.9 % vs. 8.4 %, MM = 7.7 % vs. 8.2 %), as well as a decrease in serine (AL = 17.6 % vs. 16.3 %, MM = 17.5 % vs. 15.8 %), lysine (AL = 4.8 % vs. 4.2 %, MM = 6.0 % vs. 5.4 %) and tyrosine (AL = 5.5 vs. 4.8, MM = 4.9 % vs. 4.4 %) was noted in the complete LC.

Taken IGLV6-57 separately, an increase in alanine (7.9 % vs. 8.5 %), arginine (2.4 % vs. 3.0 %), and a decrease for asparagine (4.2 % vs. 3.6 %) in comparison to the reference was noted. In the IGLV2-23 sequences, the only exclusive difference was noted concerning valine which displayed a decrease compared to the reference (6.9 % vs. 6.3 %).

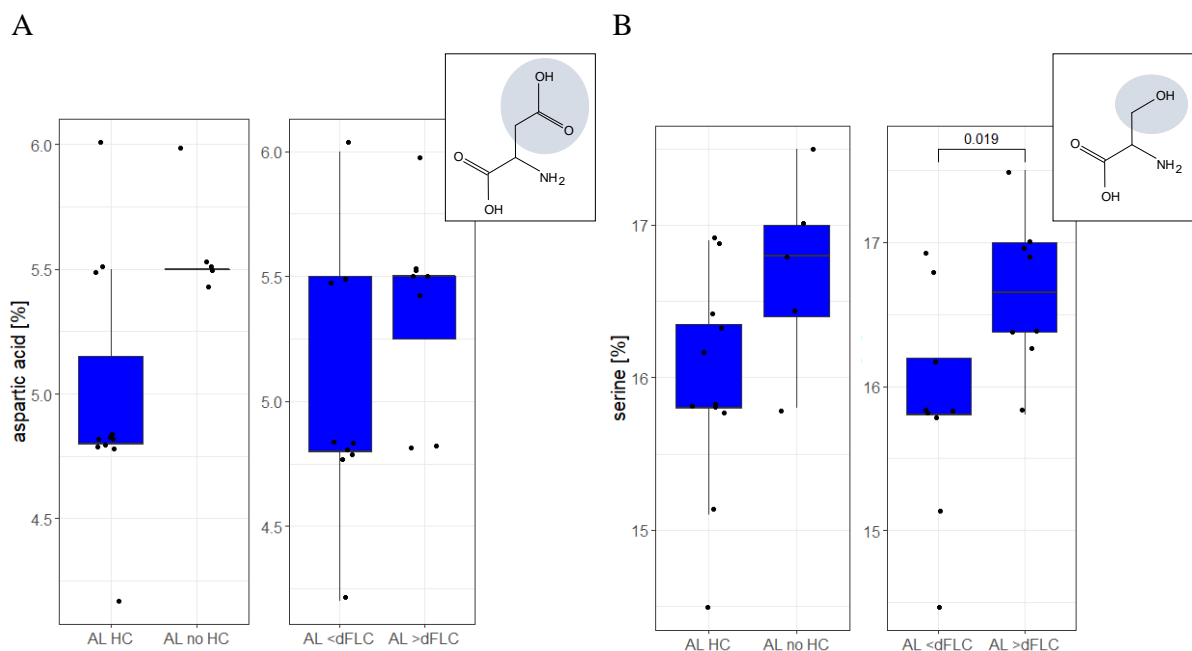

Considering the AL IGLV6-57 organ tropism separately, the AL\_H sequences presented a higher amount of arginine, aspartic acid, and isoleucine (3.6 % vs. 3.0 %,  $p = 0.047$  (t-test)) as well as a lower amount of histidine, and lysine (4.2 % vs. 4.8 %,  $p = 0.031$  (t-test)) than the AL\_HK sequences (**Figure 30**). In the AL\_HTX sequences, a lower amount of glycine and a

higher amount of serine and phenylalanine than in the AL\_H and AL\_HK sequences were detected.

**Figure 30. Comparison of the overall isoleucine and lysine percentage between IGLV6-57 assigned AL amyloidosis light chain sequences corresponding to patients with dominant heart or dominant heart and kidney involvement.** The amino acid percentage was calculated using the complete trimmed light chain sequence. AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement.

For the AAs aspartic acid and serine, a difference was observed between the AL subgroups in both the stratification for the presence of a HC and a dFLC >180 mg/L. While the AL\_H HC sequences presented a lower percentage (aspartic acid = 4.8 % vs. 5.5 %, serine = 16.0 % vs. 16.8 %), a higher percentage was noted in the AL > dFLC sequences (aspartic acid = 5.5 % vs. 4.8 %, serine = 16.7 % vs. 15.8 %  $p = 0.012$  (t-test)) (**Figure 31**). In addition, AL\_H HC sequences showed a higher proportion of valine than AL\_H no HC sequences. In AL > dFLC sequences, a higher percentage of alanine (8.5 % vs. 7.9 %;  $p = 0.015$  (U-test)), arginine, glutamine, and a lower percentage of lysine, and tryptophan than in the respective other subgroup was noted.

**Figure 31. Comparison of the overall amino acid percentage of serine and aspartic acid between IGLV6-57 assigned AL amyloidosis light chain sequences with respect to the presence or absence of a clonal HC or a dFLC >180 mg/L.** The amino acid percentage was calculated using the complete trimmed light chain sequence. MM = multiple myeloma patients, AL = AL amyloidosis patients, HC = heavy chain, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L.

### 3.7.5 Biophysical Parameters

*Several parameters were calculated to evaluate the effect of the mutations and amino acid composition on the biophysical properties of the LCs. The AGG parameter was included to determine the tendency for a beta sheet aggregation. The grand average of hydropathicity (GRAVY) value is defined by the sum of hydropathy values of all AA divided by the protein length. A negative GRAVY-value indicates a hydrophilic nature and a possible interaction of the linear protein with water molecules. The pI was also calculated to examine the theoretical stability of the LCs. In this context, the pI of the patient-derived LCs itself and the difference in comparison to a reference sequence ( $\Delta pI$ ) was calculated. This was performed for the complete LC (IGLVJC) and the IGLV and IGLJ segments (IGLVJ). In addition, the average molecular weight (Mw) of the LCs was specified.*

In the IGLV2-23 reference sequence, a higher aggregation tendency (AGG score; 126 vs. 55) as well as a lower Mw than for the IGLV6-57 reference can be detected (10038 vs. 10643) (Table 31). Due to sequence trimming, a comparison between the LCs of the two diseases was not reasonable for the AGG value and the Mw. Since the GRAVY score is calculated by the sum of hydropathy values of all AAs, divided by the number of residues, a comparison between the two IGLV subfamilies can be performed. Here, a lower value was detected for the AL IGLV6-57 sequences (-0.434 vs. -0.223, reference IGLV = -0.751 vs. -0.452). Interestingly, the IGLV segment also shows a lower pI for the IGLV6-57 reference sequence than for the IGLV2-

23 reference (4.60 vs. 6.74). However, the MM IGLV2-23 full-length LC sequences displayed a more pronounced decrease in  $\Delta pI$  in the IGLVJ (-0.55) and IGLVJC segments (-1.36) than the AL IGLV6-57 sequences (IGLVJC = -0.14, IGLVJ = 0.05).

A higher beta sheet aggregation tendency was detected in the IGLV6-57 AL\_H (814) and particularly the AL\_HTX (867) sequences compared to AL\_HK sequences (655) (**Table 31**). In addition, the AL\_H HC sequences presented a higher AGG value than the AL\_H no HC sequences (852 vs. 762). No difference was found when stratifying for a dFLC >180 mg/L.

In the analysis of the GRAVY score, no major differences were found concerning the AL organ tropism, the presence of a HC, or a dFLC value >180 mg/L (**Table 31**).

Regarding the pI, the AL\_HK sequences displayed almost no changes in pI and  $\Delta pI$  in the full-length LC, while in the AL\_H sequences a decrease was noted (**Table 31**). This difference was especially prominent when considering the AL\_HTX sequences (pI IGLVJC 4.99 vs. 4.72,  $p = 0.043$  (Median); pI IGLVJ 4.36 vs. 4.68,  $p = 0.043$  (Median)). When stratifying for the presence or absence of a HC binding partner or a > dFLC, no difference for the pI or  $\Delta pI$  was found in the AL sequences.

In the context of the Mw, no difference was detected when stratifying the AL sequence for a dominant organ involvement or the presence of a clonal HC. However, the AL > dFLC sequences displayed a higher average Mw than the AL < dFLC sequences (17712 vs. 17562) (**Table 31**).

**Table 31. Overview and comparison between different biophysical parameters of IGLV6-57 assigned AL amyloidosis and IGLV2-23 assigned multiple myeloma light chain sequences and between different subgroups.** AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, AL\_HTX = AL amyloidosis patients who received a heart transplant, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, AGG =  $\beta$ -sheet aggregation tendency, GRAVY = grand average of hydropathicity, pI = isoelectric point,  $\Delta pI$  = difference between the light chain sequence and the respective reference sequence, IGLVJC = trimmed full-length light chain, IGLVJ = connected IGLV and IGLJ segments, Mw = average molecular weight.

	median AGG	median GRAVY	pI IGLVJC	$\Delta pI$ IGLVJC	pI IGLVJ	$\Delta pI$ IGLVJ	Mw (average)

### 3.7.6 Summary IGLV6-57 and IGLV2-23

In the analysis regarding the IGLV subfamily usage between AL and MM, the most prominent differences were found concerning IGLV6-57 and IGLV2-23. IGLV6-57 was detected almost exclusively in AL and was even the most commonly used IGLV subfamily (21 % vs. 8 %;  $p = 0.001$ ). In contrast, IGLV2-23 was detected exclusively in the MM cohort and as one of the most used IGLV subfamilies (0 % vs. 15 %;  $p = <0.001$ ). Both IGLV subfamilies share a preferred linkage with IGLJ2/IGLC2. However, while the IGLV2-23 MM sequences were associated with a detectable clonal HC in serum, the AL IGLV6-57 sequences seem to relate to the no HC, < dFLC (AL\_H  $p = 0.038$ ), and AL\_HK subgroups.

In a more detailed analysis, the IGLV2-23 MM ( $n = 8$ ) sequences presented a significantly higher median mutation count in the IGLV segment than the AL IGLV6-57 sequences ( $n = 18$ ) (trimmed = 11.5 vs. 6.0;  $p = 1.60e-06$ ) – including the CDR1 (3.5 vs. 1.0;  $p = 0.003$ ), CDR2 (88 % vs. 53 %;  $p = 0.027$ ), and FR3 region (100 % vs. 65 %;  $p = 0.023$ ). This finding was further reflected in more mutation hotspots (8 vs. 1), especially in the CDR regions of MM sequences. Despite three frequently mutated positions in both cohorts, charged amino acids differed between the IGLV subfamilies. The AL IGLV6-57 sequences showed an additional charge in the CDR1 (10/18), CDR2 (8/18), and CDR3 (9/18) region, whereas, in the MM IGLV2-23 sequences, only the CDR3 region presented an additional charge. Moreover, the IGLV6-57 reference sequence generally contains a higher proportion of the negatively charged AA aspartic acid (6.1 % vs. 3.1 %) and the positively charged AA arginine (4.0 % vs. 2.1 %). However, in the overall amino acid composition of the LCs, both cohorts share several changes compared to the respective reference sequence. Taken IGLV6-57 separately, an increase in alanine and arginine as well as a decrease in asparagine was noted compared to the reference. In the IGLV2-23 sequences, the only exclusive difference was detected for valine, with a decrease compared to the reference (6.9 % vs. 6.3 %). Differences between the reference sequences were not only detected in the overall AA composition but also in the biophysical parameters. Considering only the IGLV segment, the IGLV2-23 reference shows a higher beta

sheet aggregation tendency as well as a higher pI than the IGLV6-57 reference. In contrast, a higher Mw was detected in the IGLV6-57 reference. In the analysis of the patient-derived LCs regarding the  $\Delta$ pI value, it is noticeable that while the MM IGLV2-23 sequences displayed almost no change compared to the reference sequence, a decrease was found in the IGLV6-57 AL LCs. This was not only observed in the complete LC (IGLV6-57 AL = -1.36, IGLV2-23 MM = -0.14) but also for the IGLV-IGLJ segments (IGLV6-57 AL = -0.55, IGLV2-23 MM = 0.05). In addition, a higher GRAVY score was detected for the IGLV2-23 MM sequences than for the IGLV6-57 sequences.

Not only is the strong association of AL and IGLV6-57 prominent but a specific organ tropism was further detected. The AL\_HK sequences (n = 8) were assigned to IGLV6-57 twice as often as the AL\_H sequences (n = 10) (38 % vs. 15 %; p = 0.032). However, this was reversed in the small AL\_HTX group, which showed an IGLV6-57 sequence in half of the cases (4/8). Interestingly, AL\_H sequences and especially the AL\_HTX sequences (IGLV = 7.5, IGLJ = 75 %, IGLC = 25 %) presented a higher mutational load or frequency than the AL\_HK sequences in all segments (IGLV = 5.0, IGLJ = 25 %, IGLC = 0 %). Besides the fact that several discriminating hotspots were identified, the insertion of charge can be defined as the biggest difference between these subgroups. The CDR1 of AL\_H sequences frequently presented the insertion of negatively charged AA, while in AL\_HK sequences additional positive charges were noted (p = 0.036). In contrast, only the CDR3 of AL\_HK sequences presented an additional charge in most of the cases (6/8 vs. 3/9; p = 0.02). These sequence findings also reflected in differences regarding the overall percentage of charged AAs. The AL\_H sequences presented a higher percentage of arginine and aspartic acid as well as a lower amount of the two positively charged AAs histidine and lysine (4.2 % vs. 4.8 %, p = 0.031). These differences naturally affected the calculated biophysical parameters, especially the pI and  $\Delta$ pI. While the AL\_HK full-length sequences showed almost no changes in pI and  $\Delta$ pI, the AL\_H, especially AL\_HTX sequences, showed a decrease. This led to a significantly lower pI for the full-length LCs (pI IGLVJC 4.99 vs. 4.72, p = 0.043) and IGLVJ segments (pI IGLVJ 4.36 vs. 4.68, p = 0.043) of AL\_HTX sequences compared to AL\_HK sequences. In addition, the AL\_H (814) and especially the AL\_HTX sequences (867) presented a higher beta sheet aggregation tendency compared to AL\_HK sequences (655).

Only the AL\_H sequences were analyzed concerning a detectable clonal HC since an AL\_HK HC association was noted. The AL\_H no HC (n = 4) sequences showed an especially high mutation frequency in the IGLJ (100 % vs. 50 %) and IGLC segment (50 % vs. 0 %) as well as a higher mutation count in the IGLV segment (7.5 vs. 6.5). In a more detailed sequence

analysis, the AL\_H HC (n = 4) sequences presented a Y50F mutation in three out of four cases. Furthermore, two AL\_HTX HC cases showed a Y50F mutation and a similar exchange at position 37 from tyrosine towards phenylalanine. Overall, the AL\_H HC sequences showed a higher aggregation tendency as well as a lower percentage of aspartic acid and serine and a higher percentage of valine than AL\_H no HC sequences.

Comparing the AL dFLC subgroups, the > dFLC subgroup (n = 8) showed a higher median mutation count in the IGLJ-segment (2.0 vs. 1.0) and a lower median mutation count in the FR3 (1.0 vs. 2.5). Interestingly, the Y50F mutation was associated with AL\_H HC and AL\_HTX HC and further detected exclusively in the < dFLC subgroup (n = 9). In general, for the AL > dFLC subgroup, a higher percentage of serine (16.7 % vs. 15.8 %; p = 0.012) and alanine (8.5 % vs. 7.9 %; p = 0.015) was noted. Concerning the biophysical parameters, only a difference in molecular weight was detected – which was higher in the > dFLC subgroup.

### 3.8 Summary of Common IGLV Subfamilies

Each frequently detected IGLV subfamily was associated with either a specific subgroup like a present HC, a dFLC >180 mg/L, or a distinct organ tropism in AL. However, no common pattern or discrimination between AL and MM was found (**Table 32**). In the following summary, IGLV3-21 will be neglected, since the majority of sequence features could not be evaluated.

To examine whether the difference in the LC behavior is based on a difference in the general mutation distribution and frequency, these aspects were analyzed within the IGL segments. Regarding the IGLV mutation count, it is noticeable that the MM sequences presented a median mutation count of 11.5-12.0 in all three analyzed IGLV subfamilies. In contrast, the AL IGLV6-57 subfamily displayed the lowest value with 6.0, followed by AL IGLV3-1 sequences with 7.0, and AL IGLV2-14 sequences with 8.5. If evaluable, the FR1 presented as the least frequently mutated region (IGLV3-1, IGLV2-14, IGLV2-23).

Analyzing the IGLJ segment mutation frequency between AL and MM, no difference >30 % was detected. Overall, the AL IGLV6-57 sequences presented the lowest IGLJ mutation frequency compared to the other AL subgroups (53 % vs. 71 – 79 %). Notably, the AL\_H or AL\_HTX sequences showed an increased IGLJ mutation count/frequency compared to the AL\_HK sequences in all IGLV subfamilies.

Regarding the IGLC segment, several common observations were made. The MM IGLV2-14 and IGLV3-1 sequences presented a higher IGLC mutation frequency than the respective AL

subgroup. In addition, the AL HC sequences presented an increased mutation frequency in both IGLV subfamilies. In contrast, no difference between AL IGLV6-57 and MM IGLV2-23 sequences was noted regarding mutation frequency and IGLV6-57 AL no HC sequences showed an increased mutation frequency compared to AL HC sequences.

**Table 32. Comparison of analyzed AL amyloidosis and multiple myeloma IGLV subfamilies in the context of common associations and mutation frequency and count in the IGL segments.** AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, AL\_HTX = AL amyloidosis patients who received a heart transplant, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L, AA = amino acid, FR = framework region, CDR = complementary determining region, ↑ = increase, ↓ = decrease, \* =  $p \leq 0.05$

The increased IGLV mutation count in MM sequences was also reflected in more mutation hotspots in almost all analyzed IGLV subfamilies (**Table 33**). For example, while the IGLV2-14 AL sequences displayed only two hotspots, the MM sequences displayed nine – which also comprised the AL hotspots. In a comparison between AL IGLV6-57 and MM IGLV2-23 sequences, this was even more pronounced with one AL hotspot and eight MM hotspots.

In a more detailed sequence analysis, it was not possible to find one discriminating hotspot that was present in all or most of the AL sequences and none or only a few of the respective MM sequences. It should be highlighted that the third position of the CDR2 and the last two AAs of

the IGLV segment appear to be the most frequently mutated in all analyzed IGLV subfamilies in both diseases.

Interestingly, in the IGLV2-14 as well as IGLV3-1 sequences, it was possible to detect differences regarding the insertion or replacement of charged AAs as well as small AAs between the two diseases. The IGLV2-14 AL sequences presented additional charges in the CDR1 region and enrichment of small AAs in the CDR3 – which reflected in an overall higher percentage of glycine than in the MM sequences. In contrast, the IGLV2-14 MM sequences presented additional charges in the CDR3 and overall a higher percentage of the negatively charged AA aspartic acid. A similar phenomenon was observed in the IGLV3-1 subfamily: The AL sequences showed a loss of charge in the CDR1, the MM sequences an additional one in the CDR2 as well as a higher overall percentage of the positively charged AA arginine. For both of the diseases, a mutation towards alanine or glycine was detected at the first AA of the IGLJ segment. Interestingly, the IGLV3-1 AL HC sequences showed more often an additional alanine, and the no HC sequences a glycine. Remarkably, the IGLV2-23 MM sequences, like the IGLV2-14 MM sequences, showed additional charges in the CDR3. As a side note, it was also possible to detect an additional charge in the CDR3 of IGLV3-21 MM sequences more frequently than in the respective AL sequences (5/11 vs. 1/10).

In the analysis of IGLV6-57 AL sequences, not only the insertion of charged AAs in all CDR regions but also a specific organ tropism was noted. The IGLV6-57 AL\_H sequences presented the insertion of negatively charged AA and the AL\_HK positive ones in the CDR1. Moreover, the CDR3 region also displayed an enrichment of charged AAs which was especially prominent in AL\_HK sequences. Additionally, the AL IGLV6-57 sequences presented an increased percentage of glycine compared to the respective reference.

**Table 33. Comparison of analyzed AL amyloidosis and multiple myeloma IGLV subfamilies in the context of mutation hotspots, sequence characteristics, and the overall amino acid composition.** AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L, AA = amino acid, AL\_HTX = AL amyloidosis patients who received a heart transplant, FR = framework region, CDR = complementary determining region, ↑ = increase, ↓ = decrease, \* = p <0.05.

Several parameters were calculated to evaluate the effect of the mutations and amino acid composition on the biophysical properties of the LCs (**Table 34**). In the context of the beta-sheet aggregation tendency, the IGLV2-14 and IGLV3-1 AL HC sequences presented a higher aggregation tendency than the AL no HC sequences.

The GRAVY value is defined by the sum of hydrophathy values of all AA divided by the protein length and can therefore be compared between all subgroups. The AL IGLV6-57 sequences presented the lowest value (-0.434), which indicates the most hydrophilic nature and a possible interaction of the linear protein with water molecules. In contrast, the IGLV2-23 MM sequences presented an almost twice as high value (-0.223) and therefore the highest of all analyzed subgroups. Comparable values were observed for the AL (-0.284) and MM (-0.264) IGLV2-14 subgroups and lower values for the IGLV3-1 AL sequences (AL = -0.337, MM = -0.397).

Regarding the pI and  $\Delta$ pI, the IGLV2-14 full-length LCs sequences presented higher values than the AL subgroups. The IGLV2-14 and IGLV3-1 AL sequences showed a comparable  $\Delta$ pI value of -0.5. Overall, the IGLV2-23 MM sequences presented the lowest  $\Delta$ pI value of all analyzed IGLV subgroups, and the IGLV6-57 AL sequences the highest (-0.55 vs. -0.14).

In addition, the Mw of the LCs was calculated. Here, the MM IGLV2-14 and IGLV3-1 sequences presented a higher value compared to the respective AL sequences. Remarkably, a higher value was further observed for the > dFLC subgroup in the AL IGLV2-14 and IGLV6-57 sequences.

**Table 34. Comparison of analyzed AL amyloidosis and multiple myeloma IGLV subfamilies in the context of biophysical parameters.** AL = AL amyloidosis patients, MM = multiple myeloma patients, AL\_H = AL amyloidosis patients with dominant heart involvement, AL\_HK = AL amyloidosis patients with dominant heart and kidney involvement, HC = detectable clonal heavy chain in the immunofixation electrophoresis in serum, > dFLC = dFLC >180 mg/L, < dFLC = dFLC <180 mg/L, AA = amino acid, AL\_HTX = AL amyloidosis patient who received a heart transplant, FR = framework region, CDR = complementary determining region,  $\uparrow$  = increase,  $\downarrow$  = decrease, \* =  $p \leq 0.05$ .

### 3.9 Rare IGLV Subfamilies

#### 3.9.1 IGLV1-40

It was possible to assign one AL\_H (AL = 1 %, AL\_H = 2 % FOR138) and two MM sequences (4 %; MM104, MM140) to the IGLV1-40 subfamily (**Supplementary Information Figure 33**, **Supplementary Information Figure 34**). In the bioinformatic analysis of the MM sequence MM104, it was not possible to generate a continuous LC sequence – two sequence segments were indicated. However, this does not affect the region covered by the VBase2 reference, which was verified by Sanger sequencing (**Supplementary Information Figure 35**). The AL\_H sequence showed a total of nine mutations in the trimmed IGLV segment and one each in the IGLJ and IGLC segments. In the MM sequences, a lower number of five (MM104) and eight (MM140) mutations in the IGLV segment were detected. In addition, both MM sequences displayed a mutation from valine towards isoleucine at the second position of the IGLJ segment. A second, disease-spanning hotspot was defined at position 54S (3<sup>rd</sup> position CDR2, AL = N, MM = T).

#### 3.9.2 IGLV1-44

Despite not reaching the cut-off, IGLV1-44 was one of the frequently detected IGLV subfamilies. Five AL\_H sequences (AL = 6 %, AL\_H = 8 %) and nine MM sequences (17 %) were assigned to this subfamily.

As discussed in section 4.2, all associated MM samples showed an additional sequence\_B in the bioinformatics analysis. In sequence\_A, an additional sequence segment – leading to sequence gaps – was identified in the bioinformatic analysis in seven cases. Also, in sequence\_B several sequence sections were detected but in eight out of nine cases, only the leader region was affected. For the two sequences without an additional sequence segment in sequence\_A, no sequence that covers the complete IGLV segment N-terminal was generated (**Supplementary Information Figure 36**). Four MM samples were additionally Sanger sequenced (MM116 (**Supplementary Information Figure 37**), MM119 (**Supplementary Information Figure 38**), MM137 (**Supplementary Information Figure 39**), MM141 (**Supplementary Information Figure 40**)) and in three cases a sequence coverage with the respective sequence\_B was detected. The Sanger sequencing of MM116 led to a sequence that showed several overlapping nucleotide signals but matched the respective sequence\_B – in the majority of nucleotides. Based on these results, the corresponding MM sequence\_B was used for the analysis.

The AL and MM sequences presented a comparable mutation count and frequency of the IGLJ (AL = 4/5, range 0 – 2; MM = 6/8, range 0 – 2) and IGLC segment (AL = 2/5, range 0 – 1;

MM = 3/8, range 0 – 1). However, a large range in the IGLV mutation count was observed in the MM compared to AL sequences (5 – 15, AL = 7 – 11) (**Supplementary Information Table 8**).

In addition, the MM sequences presented four mutation hotspots 33T (7/9, CDR1), 39Q (5/9, FR2), 51S (6/9, CDR2), 54Q (5/9, CDR2), the AL sequences only one 35N (4/5, CDR1) (Figure 32) – which was not shared with the MM cohort. For the AL hotspot 35N (4/5, 1xX), a mutation towards serine or threonine was detected twice each. In contrast, the MM sequences displayed a mutation at this position in only four out of nine cases (2x threonine, 1x serine). Position 33T was defined as the most frequently mutated position in the MM sequences (7/9) and a mutation towards proline was detected in a majority of the cases (4/7). Only one AL sequence displayed a mutation at this position (serine). At the 39Q MM hotspot, a mutation towards histidine was detected in four out of nine MM and two out of five AL cases. At position 51S, no directed exchange pattern was detected but at position 54Q a mutation towards a positively charged AA was detected in four out of nine MM cases (2x histidine, 2x arginine, AL n = 0).

Besides these IGLV mutation hotspots, the first AA of the IGLJ segment was also defined as a mutation hotspot for both diseases, and a preferred exchange towards proline was noted (AL = 4/5, MM = 5/9).

**Figure 32. Sequence sections of IGLV1-44 assigned AL amyloidosis and multiple myeloma light chain sequences.** Bold = reference sequences, underlined = CDR regions, red letter = mutation, purple highlight = mutation hotspot, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement. Only one IGLC reference is shown because the first amino acid can in all cases be defined as glycine. Amino acids were numbered according to the VBase2 reference. The complete amino acid sequence alignment is shown in Supplementary Information Figure 41. The complete cDNA sequence alignment is shown in Supplementary Information Figure 42.

### 3.9.3 IGLV1-47

One AL\_HK (AL = 1 %, AL\_HK = 5 %, FOR168) and one MM sequence (2 %, MM151) were assigned to the IGLV1-47 subfamily (**Supplementary Information Figure 43, Supplementary Information Figure 44**). In the bioinformatic analysis of the MM sequence, it was not possible to generate a continuous LC sequence and two sequence segments were indicated. However, this does not affect the region covered by the VBase2 reference. The AL\_HK sequence displayed three mutations in the IGLV segment, two in the IGLJ and one in the IGLC segment. In contrast, the MM sequence presented six mutations in the IGLV segment (including 3<sup>rd</sup> position CDR2). No position showed a mutation in both sequences.

### 3.9.4 IGLV1-51

Two AL (AL = 2 %, AL\_H 2 % FOR193, AL\_HK 5 % FOR149) and two MM sequences (4 %, MM110, MM131) of the IGLV1-51 subfamily were identified (**Supplementary Information Figure 45, Supplementary Information Figure 46**). The AL sequences displayed eleven (FOR139) and six (FOR149) mutations in the IGLV segment and one in the IGLJ segment. In MM110 six mutations and in MM131 five mutations were detected in the IGLV segment and two (MM110) or four mutations (MM131) in the IGLJ segment. A mutation in the IGLC segment was not detected in all cases. In a detailed sequence analysis, two positions are noticeable: the exchange N53D (3<sup>rd</sup> position CDR2, AL = 2/2, MM = 1/2) and an undirected exchange at the first position of the IGLJ segment.

### 3.9.5 IGLV2-8

One AL\_H (2 %, FOR182) and one AL\_HK (4 %, FOR164) sequence were assigned to IGLV2-8 (AL = 2 %) and no MM sequence (**Supplementary Information Figure 47, Supplementary Information Figure 48**). The AL\_H sequence displayed ten mutations in the IGLV segment and one in the IGLJ segment. In contrast, the AL\_HK sequence contained only six mutations in the IGLV segment. The sequences shared three mutated positions (27S, 49M, and 54S (3<sup>rd</sup> position CDR2)). Interestingly, both sequences displayed an exchange towards isoleucine at position 49M.

### 3.9.6 IGLV2-11

Only one MM sequence (2 %, MM127) was assigned to the IGLV2-11 subfamily (**Supplementary Information Figure 49, Supplementary Information Figure 50**). In general, four mutations in the IGLV segment, including the third position in the CDR2 (S54T) as well as one mutation in the IGLJ segment, were detected. Additional Sanger sequencing

verified most of the cDNA positions but some nucleotide signal overlaps were noted (**Supplementary Information Figure 51**).

#### 3.9.7 IGLV3-19

Three AL\_H (AL = 4 %, AL\_H = 5 %; FOR103, FOR148, FOR216) and two MM sequences (4 %; MM128, MM145) were assigned to the IGLV3-19 subfamily (**Supplementary Information Figure 52, Supplementary Information Figure 53**). The MM128 sequence was verified through additional Sanger sequencing (**Supplementary Information Figure 54**). The AL sequences were missing seven (2/3) or eight (1/3) AAs at the N-terminus of the IGLV segment due to the oligonucleotide binding site. FOR103 displayed four mutations and FOR216 eight mutations in the IGLV segment as well as one mutation in the IGLJ segment. In FOR148 no mutation was detected at all, however, several AAs were not determined unambiguously. Both MM sequences showed seven mutations in the IGLV segment and shared mutations at positions 29S, 65S, and 92S. Interestingly, the MM sequences displayed a S65T mutation, while two out of three AL sequences displayed a S65N mutation. In addition, MM145 displayed three mutations in the IGLJ segment and one in the IGLC segment.

#### 3.9.8 IGLV3-25

One AL\_H (AL = 1 %, AL\_H = 2 %, FOR111) and one MM (2 %, MM105) sequence were assigned to the IGLV3-25 subfamily (**Supplementary Information Figure 55, Supplementary Information Figure 56**). However, it was not possible to generate a N-terminal elongated AL sequence and therefore no detailed sequence analysis was performed. The MM sequence displayed eleven mutations in the IGLV segment (including the 3<sup>rd</sup> CDR2 position: S51H) and none in the IGLJ and IGLC segment. It should be noted that through additional Sanger sequencing, it was not possible to generate an evaluable MM sequence.

#### 3.9.9 IGLV7-46

One MM (2 %, MM113) sequence was assigned to the IGLV7-46 subfamily (**Supplementary Information Figure 57, Supplementary Information Figure 58**). In the bioinformatic analysis, it was not possible to generate a continuous LC sequence and two sequence segments were indicated. However, only partial sequence matches were detected. It was possible to detect 15 mutations in the IGLV segment (including the 3<sup>rd</sup> CDR2 position 54S).

#### 3.9.10 IGLV8-61

Only one AL\_HK sequence (FOR229) was assigned to the IGLV8-61 subfamily (**Supplementary Information Figure 59, Supplementary Information Figure 60**). Compared to the VBase2 reference, four AAs were missing at the N-terminus due to the

oligonucleotide binding site. The sequence displayed 14 mutations in the IGLV segment as well as one in the IGLJ segment. Moreover, the sequence corresponded to an AL patient who was also diagnosed with MM.

### 3.10 Summary of Rare IGLV Subfamilies

In the analysis of the most common AL-associated IGLV subfamilies, several differences, as well as commonalities, between AL and MM were noted.

Regarding the IGLV segment, the MM sequences presented a significantly higher mutation count than the respective AL subgroups. Interestingly, all analyzed IGLV subfamilies showed a comparable median mutation count of 11.5-12.0 in the MM sequences, which did not reflect in the other, rarer, IGLV subfamilies (**Table 35**). Furthermore, the higher mutation frequency of MM sequences in the IGLC segment, could not be unambiguously noted for the remaining IGLV subfamilies. In contrast, AL and MM sequences of less common IGLV subfamilies also frequently presented the mutation hotspot at the third position of the CDR2 region.

AL and MM sequences frequently showed differences in charge and small AAs which was also noted for the IGLV1-44 subfamily. Despite not reaching the cut-off, IGLV1-44 was one of the frequently detected IGLV subfamilies, comprising five AL and nine MM sequences. While four MM cases presented a mutation towards a positively charged AA at position 54Q, this was not observed in the AL cohort. Interestingly, besides the shared mutation hotspot at the first AA of the IGLJ segment and a prominent exchange towards proline, the MM sequences further presented a T33P mutation in more than half of the cases.

**Table 35. Comparison of relative rare AL amyloidosis and multiple myeloma associated IGLV subfamilies in context of mutations, and sequence features.** In the case of IGLV1-44, a mutation range was specified. AL = AL amyloidosis patients, MM = multiple myeloma patients, + = positively charged amino acid, , NA= not available, CDR = complementary determining region, → = mutation towards.

	n		Mutation count [n]						Mutation 3 <sup>rd</sup> CDR2 position		private sequence features	
			IGLV		IGLJ		IGLC		AL	MM	AL	MM
	AL	MM	AL	MM	AL	MM	AL	MM	AL	MM	AL	MM
IGLV1-40	1	2	9	5, 8	1	1, 1	1	0, 0	S54N	S54T		IGLJ 3 <sup>rd</sup> →I/V
IGLV1-44	5	9	7 – 11	5 – 15	0 – 2	0 – 2	0 – 1	0 – 1	no	no	35N	T33P, Q54+,
IGLV1-47	1	1	3	6	2	0	1	0	no	N53D		
IGLV1-51	2	2	6, 11	5, 6	1	2, 4	0	0	N53D	N53D (1/2)	no	no

	n		Mutation count [n]						Mutation 3 <sup>rd</sup> CDR2 position		private sequence features	
	AL	MM	IGLV		IGLJ		IGLC		AL	MM	AL	MM
IGLV2-8	2	0	6, 10		0, 1		0, 0		54S		M49I	
IGLV2-11	0	1		4		1		0		S54T		
IGLV3-19	3	2	0, 8	7, 7	0, 1	0, 3	0	0, 1	no	no	S65N	S65T
IGLV3-25	1	1	NA	11	NA	0	NA	0	NA	S51H	NA	
IGLV7-46	0	1		15		0		0		S54D		
IGLV8-61	1	0	14		1		0		no			

Based on the analysis of the relatively rare AL as well as MM-associated IGLV subfamilies, no new insights were gained beyond those already obtained above. However, the results concerning IGLV1-44 supported the findings regarding a difference in charge and small AAs between AL and MM.

## 4 Discussion

This study aimed to investigate AL-specific lambda LC sequence features to I) draw conclusions on the pathogenic mechanism and II) establish a risk stratification for disease progression from MGUS/SMM/MM towards AL. For these analyses, MM sequences were used as reference set since AL and MM patients usually display an increased level of free LCs but those of MM patients do not deposit as fibrils.

### Summary Key-Note Results

#### Cohorts:

- 52 MM patients and 82 AL patients, comprising 61 AL\_H and 21 AL\_HK patients
- stratification for a present clonal HC and dFLC > or < 180 mg/L
- more detailed analyses: IGLV2-14, IGLV3-1, IGLV3-21, IGLV6-57 and IGLV2-23

#### IGLV subfamily distribution:

- IGLV6-57 more frequent in: AL than MM\*, AL\_HK than AL\_H\*, and AL\_H < dFLC than AL\_H > dFLC\*
- IGLV2-23 more frequent in: MM than AL\*
- IGLV2-14 more frequent in: AL\_H HC than AL\_H no HC\*
- IGLV3-1 more frequent in: AL > dFLC than AL < dFLC\*

#### IGLV-IGLJ-IGLC composition:

- IGLJ2/IGLC2 most frequent linkage for AL and MM
- IGLV3-21 AL: IGLJ2/IGLC2 and IGLJ3/IGLC3 equally frequent

#### IGLV3-21 subfamily (AL):

- large number of ambiguously identified AA and LCs N-terminal only amplified starting from FR2 → additional NGS experiments
- MP\_NGS\_PCR: verification of the IGLV3-21 assignment and sequences itself
- N\_NGS\_PCR: no additional insights could be gained

#### Mutation count and frequency:

- IGLV: higher in MM than AL LCs\*
- IGLJ: no major differences between AL and MM LCs; higher in AL\_H than AL\_HK LCs
- IGLC: IGLV2-14: higher in MM than AL LCs;  
IGLV2-14 and IGLV3-1: higher in AL HC than AL no HC LCs

#### Mutation hotspots and AA composition:

- more mutation hotspots in MM than AL LCs
- higher percentage of charged AA in IGLV2-14 (D) and IGLV3-1 (R) MM than AL LCs
- differences concerning charged and small AAs between AL and MM LCs: IGLV2-14\*, IGLV3-1, IGLV3-21, and IGLV1-44
- differences concerning charged AAs between IGLV6-57 AL\_H and AL\_HK\*

#### Biophysical parameters:

- AGG: higher for IGLV2-14 and IGLV3-1 AL HC than AL no HC LCs
- GRAVY score: no significant differences between AL and MM LCs;  
IGLV6-57 LCs the lowest value and IGLV2-23 LCs the highest value
- pI and ΔpI: IGLV2-14 MM higher pI than AL full-length LCs;  
IGLV2-23 MM LCs the lowest ΔpI value and IGLV6-57 AL LCs the highest
- Mw: IGLV2-14 and IGLV3-1 MM higher than AL LCs;  
higher for IGLV2-14 and IGLV6-57 AL > dFLC than AL < dFLC LCs

## 4.1 How to be Sure to Sequence the Amyloidogenic Clone?

### 4.1.1 Verification Steps

Before evaluating and discussing more detailed sequence characteristics, a more fundamental question shall be considered first: how to be sure to sequence the amyloidogenic clone? In this context, a profound advantage of this study was sequencing cDNA from CD138<sup>+</sup> sorted plasma cells. Using this starting material, it is assumed that the analyzed samples contain a high proportion of clonal cells and can therefore in general reflect the disease-associated clone (Chilosi et al. 1999; Kriegsmann et al. 2018; Ridley et al. 1993; Wijdenes et al. 1996)).

Additionally, within the framework of this study, four different approaches were used to verify the sequencing results: (A) The initial development of a full-length lambda LC sequencing protocol included the first verification step. Here, four different oligonucleotide combinations were used to sequence FOR101 and FOR102 and it was possible to detect the same underlying LC sequence in all cases (chapter 2.6.4). (B) An additional verification step was necessary since the MM sequences were obtained through a different sequencing approach. Sanger sequencing of several MM LCs verified not only the MM sequences but further the AL method and oligonucleotides. (C) IGLV3-21 proved to be the most difficult AL lambda IGLV subfamily to sequence, and additional NGS experiments were performed. Here, the MP\_NGS\_PCR approach verified both the family assignment and the sequences. (D) It was possible to demonstrate that the generated LC sequences match the amyloidogenic protein in the patients, which will be explained in the following paragraph in more detail.

This fourth verification step was feasible due to a collaboration with a research group at Ulm University headed by Prof. Dr. rer. nat. Markus Fändrich and Dr. rer. nat. Christian Haupt. Determining the amyloid load in abdominal fat aspirates is a standard tool for supporting an AL diagnosis and further evaluating the prognosis (van Gameren et al. 2010). These fat samples were obtained from all patients treated at the amyloidosis center in Heidelberg and analyzed for their amyloid load. If a high amyloid load in the fat aspirates and an analyzable LC sequence were present, these fat samples were sent to Ulm. In the next step, Julian Baur (Ulm University) extracted the underlying amyloidogenic proteins from these fat samples and additionally from heart tissues. These heart tissues were obtained from heart transplants donated for research. In total, 54 lambda sequences and corresponding samples were sent to Ulm. This sample set comprised 34 AL\_H samples, eight AL\_HK samples, nine samples from AL patients with dominant kidney involvement (AL\_K), and three samples from AL patients with no dominant heart, kidney, or heart and kidney manifestation (AL\_D). Based on this dataset, ten sequences and corresponding proteins were analyzed in more detail (Baur et al. 2022). This concerned

eight sequences that were generated within the framework of this work (6x AL\_H, 2x AL\_K) and in collaboration with Sarah Schreiner (University Hospital Heidelberg, AL\_K and AL\_D sequences). The two remaining sequences and samples were already analyzed through cryo-EM and corresponded to AL\_HTX patients (FOR005 (Radamaker et al. 2021a), FOR006 (Radamaker et al. 2019)).

These eight extracted proteins were analyzed by mass spectrometry and the provided sequences corresponded well to the actual amyloidogenic protein. Further, the proteins comprised the IGLV segment, IGLJ segment, and up to 14 AAs of the IGLC segment (Baur et al. 2022). It is worth mentioning that it was possible to verify sequences from three different IGLV families and four IGLV subfamilies: IGLV1-40, IGLV1-44, IGLV2-14, and IGLV3-19. As a side note, the AA sequence of three cases (FOR101, FOR142, FOR159) contained ambiguous AA positions. These positions were resolved by mass spectrometry data and identified within one of the two AA possibilities that resulted from the cDNA sequencing (Baur et al. 2022). However, the cDNA sequence was still crucial since it was not always possible to extract enough protein from the fat samples to generate a complete sequence coverage by the mass spectrometry results. Another problem of mass spectrometry is that leucine and isoleucine, due to the same Mw, cannot be distinguished from each other.

Summarizing, these four approaches verified the IGL family assignment and the cDNA sequence. Further, the sequences correspond well to the deposited AL protein in the patients, so it can be considered that they reflect the amyloidogenic clone.

#### 4.1.2 Challenges

One of the hallmarks of LCs is their high variability and several mechanisms are intertwined to ensure this. Not only does this concern the junctional diversity and somatic hypermutations, but also the combinatorial diversity. Up to 36 different IGLV, four IGLJ, and four IGLC genes, each can be potentially combined to finally lead to a functional lambda LC (Kawasaki et al. 1997; Lefranc and Lefranc 2020; Schroeder and Cavacini 2010). Additionally, although a dominant sequence in AL can be assumed, there is nevertheless a certain degree of sequence and respective clonal heterogeneity (Bochtler et al. 2018).

In this context, PCR-based Sanger sequencing is expected to map a certain degree of sequence heterogeneity. However, applying this method may also mean that some LC sequences will be difficult or even impossible to resolve. In the scope of this work, only 10 % (8/82) of the

generated LC sequences were not assigned to an IGLV segment, which not always concerned a not evaluable sequence. Here, cases in which specific mutations do not allow a clear distinction between two reference IGLV segments were also included.

Further, only 15 % (12/82) of the generated LC sequences showed at least ten not clearly identified AAs. In this context, in particular, the IGLV3-21 subfamily was prominent. IGLV3-21 was detected frequently in both AL and MM but AL full-length LC sequencing proved difficult. The AL sequences showed an above-average number of sequence blurs and several oligonucleotides failed to bind in FR1. In contrast, it was possible to resolve three MM sequences N-terminally and to generate a sequence without uncertain nucleotide positions twice. So, it can be postulated that the sequencing difficulties probably only relate to AL sequences. These difficulties could be caused by a mutation, insertion, or deletion that could be common or even exclusively characteristic of AL and prevent oligonucleotide binding. Interestingly, IGLV3-21 is the only detected IGLV gene that comprises three instead of only two exons – however, the first exon is described as noncoding (Ensembl). In this context, amplification could further be prevented by different splicing variants since the oligonucleotide binding site is located at the beginning of the third exon.

The IGLV3-21 next-generation sequencing experiments performed within this work demonstrated that the sequences can be assigned unambiguously to IGLV3-21 and the MP\_NGS\_PCR approach even verified the Sanger sequences. In contrast, the N\_NGS\_PCR approach only conditionally detected IGLV3-21 sequences. However, the positive control showed that the PCR protocol works in principle.

Nevertheless, the phenomenon of prominent sequence blurs in certain IGLV subfamilies and lacking oligonucleotide binding, should be studied in more detail. Bulk RNA sequencing could be helpful to investigate not only the sequences but also the composition of the expressed LCs in more detail. This approach would also shed light on the intra-clonal heterogeneity and provide more information about the actual diversity of the expressed LCs in a single AL patient.

Summarizing, within this work, 90 % of the AL LCs were assigned to a specific IGLV segment and 85 % of the sequence showed only a few uncertain AA positions.

#### **4.2 Discrimination between Amyloidogenic and Non-Amyloidogenic Light Chains**

This work primary aimed to investigate and define AL-specific lambda LC sequence features – mostly in comparison to MM lambda LCs. In the first step, both cohorts were clinically

characterized and met the expectations. Therefore, it is assumed that these are representative groups, with one limitation: The AL cohort only comprised AL\_H and AL\_HK patients, to perform an analysis regarding the characteristic organ tropism. In the following chapter, the identified communalities and differences between the two diseases will be discussed and put into context, to potentially infer on pathogenic mechanisms.

#### 4.2.1 IGLV Subfamily Usage

After the clinical characterization, the IGLV subfamily usage was investigated to examine if the IGLV families present a difference in their amyloidogenic potential. Several studies have been published to address this aspect (Abraham et al. 2003; Comenzo et al. 2001; Kourelis et al. 2020; Perfetti et al. 2002; Perfetti et al. 2012; Sidana et al. 2021). The comparison of five of them showed that IGLV6-57 and IGLV3-1 are the most frequently AL-associated IGLV subfamilies. Additionally, IGLV2-14 was among the commonly AL-associated IGLV subfamilies in three out of five studies (Kourelis et al. 2017; Perfetti et al. 2012; Sidana et al. 2021). The data set presented in this work is well in line with previously published preliminary data, which also included AL\_K patients (Berghaus et al. 2022; AL\_K patients were analyzed by Sarah Schreiner (University Hospital Heidelberg)).

Despite the comprehensive data about IGL families in AL, the analysis of exclusively AL sequences is insufficient to conclude on associations and potential crucial sequence features. Past work usually used healthy donors or LC sequences stored in the "AL-Base" database as a reference set. The advantage of this study is the comparison of LC sequences from clinically well-characterized AL and MM cohorts. The MM patients were treated within the GMMG-HD6 clinical trial and screened for amyloid deposits as potential exclusion criteria. Later progression to AL is a very rare phenomenon but cannot be precluded. Nevertheless, the median follow-up of the GMMG-HD6 trial was 49.8 month (Goldschmidt et al. 2021) and in total, one out of 564 patients was excluded due to developing an amyloidosis during this trial (unpublished data). This excluded MM patient presented a kappa LC and was therefore not part of the cohort analyzed within this work. So, an actual comparison of amyloidogenic and non-amyloidogenic LCs is assumed.

Two remarkable results from the comparison of AL and MM LC sequences, are a significant association of IGLV6-57 with AL LCs and the exclusive detection of IGLV2-23 for MM LCs. To compare the results of this study with a larger data set, LCs deposited in AL-Base were utilized. AL-Base is an internet LC database, established and hosted by the Boston University (the Amyloidosis Center at the Boston University School of Medicine) (Bodi et al. 2009). The stored LC sequences are classified into three major clinical groups "AL – plasma cell disorder",

"other – plasma cell disorders" and "non – plasma cell disorders", which can be further specified in e.g. "AL", "MM" or "healthy individual". Additionally, the LC sequences can be sorted by kappa and lambda and the corresponding IGV subfamilies (Bodi et al. 2009). Analyzing the deposited lambda AL (n = 416) and MM sequences (n = 91), an AL IGLV6-57 association was most frequently detected, namely in 24 % of the AL cases and only in 2 % of the MM cases. In contrast, AL sequences showed an IGLV2-23 assignment in only 3 % and MM sequences in 10 %. Thus, the data deposited in AL-Base also showed a striking difference for these two IGLV subfamilies. However, AL-Base is not a completely curated database. The stored LC sequences cannot always be assigned to a publication, which means that the methodology used is also unknown. Further, the length of the sequences varies and information about clinical parameters are usually not available.

Even though this work focused on only AL\_H and AL\_HK patients, an association of certain IGLV subfamilies with a specific type of organ involvement should be discussed in more detail. All studies cited above, which investigated the organ tropism, coincided with the enrichment of IGLV2-14, IGLV1-40, and especially IGLV6-57 for AL\_K patients. The analysis regarding AL\_H patients presented more varieties. Here, most prominent LCs of the IGLV2-14 and IGLV1-44 subfamilies were detected (followed by IGLV3-1 and IGLV3-21) (Abraham et al. 2003; Comenzo et al. 2001; Kourelis et al. 2020; Perfetti et al. 2002; Perfetti et al. 2012; Sidana et al. 2021). Within this work, a prominent association for IGLV3-1 and IGLV3-21 with AL\_H as well as for IGLV6-57 with AL\_HK was noted. Interestingly, IGLV6-57 was also detected for four out of eight AL\_HTX LCs. The previously published own preliminary dataset is well in line with these observations (Berghaus et al. 2022; AL\_K patients were analyzed by Sarah Schreiner (University Hospital Heidelberg)).

Certain trends can be noted when comparing the AL\_H and AL\_HK data of this work with own previously published AL\_K data (Berghaus et al. 2022; AL\_K patients were analyzed by Sarah Schreiner (University Hospital Heidelberg)). IGLV1 showed a more pronounced association with AL\_K sequences. The IGLV2 subfamilies were found commonly in AL\_H and AL\_K and less in AL\_HK sequences; the IGLV3 subfamilies seemed to be more associated with AL\_H sequences. In contrast, the IGLV6-57 subfamily was detected equally frequently in AL\_H and AL\_K sequences and noticeable more often in the AL\_HK sequence (Berghaus et al. 2022; AL\_K patients were analyzed by Sarah Schreiner (University Hospital Heidelberg)). Accordingly, this strengthens the hypothesis that a divergent amyloidogenic potential in general but even an association towards an organ involvement can be assumed.

In addition to the organ tropism, the sequences were further stratified for a potential HC binding partner and, concerning tumor size and malignancy, for a dFLC >180 mg/L. Interestingly, IGLV2-14 was detected significant more often in AL\_H HC cases, and IGLV6-57 in AL\_H < dFLC cases. More general, IGLV3-1 was more frequently detected in the AL > dFLC subgroup. These aspects might influence a risk stratification based on the respective IGLV subfamily. The analyses concerning the stratifications for a present clonal HC and the dFLC will be addressed in a more detailed manner in chapter 4.3.

To conclude, the results of this study support the assumption that IGLV subfamilies present a difference in their amyloidogenic potential and are well in line with previously published studies and the data deposited in AL-Base. Additionally, certain associations were not only detected for AL and MM but also for AL\_H, AL\_HK, when stratifying for the presence or absence of a clonal HC, and a dFLC >180 mg/L. Therefore, it can be postulated that certain IGLV subfamilies may display favorable characteristics for different pathogenic mechanism.

#### 4.2.2 Mutation Frequency and Count

The already addressed IGLV subfamily usage is part of the combinatorial diversity, a mechanism to increase the LC diversity. This LC diversity is even further increased through junctional diversity and somatic hypermutations. It is assumed, that the introduced mutations and changes can increase the LC capability/propensity to aggregate and form fibrils (Blancas-Mejía and Ramirez-Alvarado 2013). To address this assumption, the AL and MM LC sequences were analyzed for their median mutation count and frequency.

It was striking at this point that all MM LCs displayed a median of 11.5 – 12.0 mutations in the IGLV segment. Even though the sequences were trimmed differently, the affected FR1 region was defined as the least mutated region in several IGLV subfamilies. Thus, the results can be placed in a comparative framework. In this analysis, the AL sequences showed significantly fewer mutations than the MM sequences. Further, the IGLV2-14 and IGLV3-1 MM sequences also presented a higher mutation frequency in the IGLC segment than the respective AL sequences. These findings contradict the hypothesis that an excessive accumulation of mutations leads to destabilization and misfolding of the AL-associated LCs.

An explanation for this difference between AL and MM might be that an excessive mutation rate due to genomic instability can be hypothesized for MM. In a study published by Walker et al., 37/40 MM patients showed an indicator for DNA double-strand breaks in plasma cells

(Walters et al. 2011). DNA double-strand breaks can lead to CA and thus potentially to genomic instability and, ultimately, to cancer (Walters et al. 2011). This could serve as a preliminary explanation for the higher mutational load compared to AL LCs. However, no statement about the actual germline of the patients can be made, since cDNA was sequenced within this work. Another hypothesis might be that MM is associated with a larger and therefore also even further evolved tumor clone than the ones observed in AL. In this context, it was already shown that during the tumor evolution from MGUS towards MM mutations are acquired (Walker et al. 2014), which could then serve as additional or alternative explanation for the differences between AL and MM.

Apart from the differences between AL and MM, the AL IGLV subfamilies also differed in their median mutation count. In general, a range of four up to fifteen mutations compared to a respective reference was reported for AL-associated LCs, more precisely the VL domain (Absmeier et al. 2022). In this study, IGL subfamily-dependent median mutation counts, within the range of four up to fifteen mutations, were detected.

IGLV2-14 LC sequences displayed the highest value, followed by IGLV3-1, and IGLV6-57 LCs the lowest. Here, it must be considered that IGLV2-14 is one of the most frequently detected AL and MM IGLV subfamilies, IGLV3-1 has been associated with AL more frequently, and most importantly that IGLV6-57 was detected almost exclusively in the AL cohort. Based on these results, several alternative hypotheses can be postulated which complement the assumption that certain IGLV families display already primary favorable properties for the amyloid formation: a) fewer mutations are sufficient to increase the aggregation capability of inherent aggregation prone IGLV subfamilies b) the increased mutation count in MM LCs might lower their aggregation potential c) it can be assumed that a certain number of mutations are necessary to form a functional LC.

To confirm the hypothesis of divergent primarily favorable amyloidogenic properties of IGLV subfamilies, the 'normal' IGLV repertoire of healthy individuals or other plasma cell disorders need to be analyzed. The data deposited in AL-Base concerning plasma cells and categorized as "normal repertoire" (n = 102) displays IGLV6-57 in 14 % of the cases and most frequently IGLV1-44 or IGLV3-19 (both 16 %). At first sight, this seems to contradict the hypothesis but again, it must be considered that the source of the deposited sequences is not validated and is only partially reproducible. This is also reflected in the median mutation counts of the IGLV6-57 LCs classified as "normal repertoire". Here, the sequences showed a range from zero (2x) up to 19 mutations (in the analyzed AA range of this work). Nevertheless, the median mutation count was with 8.5 higher than the median mutation count of the AL IGLV6-57

sequences in this work. This might support the hypothesis, that a certain number of mutations must be acquired to form a functional LC. Ultimately, the analysis of a larger study with a well-characterized cohort is needed to confirm or reject the hypotheses.

Sequencing not only the IGLV segment but the complete LC was an important step forward of this study. In this analysis, the IGLV segment and also the IGLC segment were mutated more frequently in MM than in AL sequences. This finding might also correlate with an assumed increased genomic instability in MM patients and a possible subordinate role of the IGLC segment in fibril formation. Regarding the IGLJ segment, AL and MM sequences showed no significant differences. Here, IGLV6-57-associated AL LCs displayed a notable division. They presented approximately 20 % less frequently mutated in the IGLJ segment than AL LCs from other IGLV subfamilies. Despite the difference concerning IGLV6-57, a certain organ tropism was also noted. The AL\_H sequences always displayed a higher mutation frequency than the AL\_HK sequences of the corresponding IGLV subfamily (IGLV6-57: AL\_HTX). A reason for this phenomenon is not yet apparent, and further studies concerning the AL organ tropism and comparisons towards AL\_K and AL\_D sequences are needed.

To conclude, the results of this study contradict the assumption that an accumulation of mutations could serve as an explanation for amyloidogenity. An alternative hypothesis can be postulated based on the mutation counts, shortly summarized as “quality before quantity”.

#### 4.2.3 Mutation Hotspots and Sequence Characteristics

A more detailed analysis of the mutation hotspots and AAs exchanges was needed in the context of the postulated hypotheses. Here, the detected higher median mutation count in MM sequences was also reflected in more mutation hotspots than in the AL sequences. The low AL IGLV6-57 mutation count is also shown in this analysis since only one hotspot was identified. However, it was not possible to detect common mutation hotspots that were present exclusively in the AL sequences and would therefore discriminate between AL and MM. As side note, AL and MM sequences frequently presented the mutation hotspot at the third position of the CDR2 region, which was already described as AL hotspots in other studies (Poshusta et al. 2009; Radamaker et al. 2021b). This missing discrimination potential also concerns the IGLV-IGLJ linker region, which is part of the junctional diversity. In this context, it was also not possible to identify a disease-specific mutation pattern.

So, a more holistic approach was chosen, since the lack of clear discrimination potential by the mutation hotspots and linker region. In general, various effects of mutations that subsequently

favor the formation of fibrils can be assumed. Here, two main aspects need to be noted: a destabilizing effect that leads to the misfolding of the soluble precursor protein or a stabilizing effect of the final amyloid structure (Absmeier et al. 2022). The stabilizing effect can, for example, be achieved by interactions between stored monomers of the protofilament or within the steric zipper and cross-motifs inside the fibril core (Absmeier et al. 2022; Pradhan et al. 2020; Radamaker et al. 2019). Therefore, the insertion or deletion of charge in specific regions might induce or enhance interactions. The importance of charge was also represented in the cryo-EM structure of an IGLV1-44 fibril. Here, three mutations added charge to the surface of the fibril, one removed charge from a non-polar cavity, and one additional contributed to compensate native conserved charges. Therefore, in this case study, five out of eight mutations induced or removed charged AAs in the IGLV segment (Radamaker et al. 2019).

Strikingly, it was possible to detect differences concerning charge and small AAs between AL and MM for each IGLV subfamily analyzed within this work. Further, such differences were detected in the frequently AL-associated IGLV subfamilies (IGLV2-14, IGLV3-1, IGLV3-21) and even for IGLV1-44. These differences translated into a lower overall percentage of aspartic acid for IGLV2-14 AL and arginine for IGLV3-1 AL sequences compared to the respective MM LCs. So, individual pathogenic mechanisms for each IGLV subfamily can be hypothesized. This assumption is supported by the fact that all published fibril structures of different IGLV subfamilies showed a different morphology (Radamaker et al. 2021a; Radamaker et al. 2021b; Radamaker et al. 2019; Swuec et al. 2019).

Not only differences between AL and MM and the IGLV subfamilies but also concerning the AL organ tropism were detected. In this context, IGLV6-57 can again serve as a model to differentiate the AL<sub>H</sub> and AL<sub>HK</sub> sequences. Next to exclusive AL<sub>H</sub> or AL<sub>HK</sub> hotspots, these subgroups showed interesting differences regarding charged AAs. While both subgroups displayed an additional charge in CDR1, AL<sub>H</sub> sequences were significantly associated with an additional negative one and AL<sub>HK</sub> sequences with a positive one. Additionally, both subgroups displayed the introduction of the charge in the CDR2, and AL<sub>HK</sub> sequences exclusively showed a third additional charge in the CDR3. That these deviations are limited to the CDR regions is surprising, considering its natural function to enhance the diversity of LCs. However, others demonstrated that not only mutations in the more conserved FR regions contribute to destabilization (Hurle et al. 1994). Further, mutations in CDR regions can potentially induce structural changes or enhance backbone dynamics (Absmeier et al. 2022; Blancas-Mejía et al. 2014; Rottenaicher et al. 2021).

In conclusion, the hypothesis that IGLV families probably have an inherently divergent amyloidogenic potential can be complemented by the fact that charge might also be an important factor – not only in the context of amyloidogenicity but also for the AL organ tropism. Based on the results that each IGLV family presented a different mutation pattern, it can also be postulated that individual pathological sequence-based mechanisms may exist for each IGLV subfamily separately.

#### 4.2.4 Biophysical Parameters

Various biophysical parameters were investigated to detect an effect of the mutation patterns on the LCs. This is of interest in the context of the postulated hypothesis that different IGLV families have different inherent amyloidogenic potentials. However, a direct comparison between the patient-derived LCs and their IGLV subfamilies is only possible for the GRAVY score and  $\Delta pI$  value. This is due to the fact that the GRAVY value is calculated by the sum of hydropathy values of all AAs divided by the protein length. The  $\Delta pI$  value was determined using the difference between the patient-derived LC and a reference sequence.

The results of this study suggest a relationship between a low GRAVY score and an increased amyloidogenic potential. However, this seems to contradict the phenomena of insoluble amyloid fibrils. The MM IGLV2-23 LC sequences showed the highest value, and the AL IGLV6-57 the lowest. At first glance, this is surprising, as it would suggest that IGLV6-57 LCs are most soluble in water in the linear state. Nevertheless, more generally, a low GRAVY score indicates that more hydrophilic AAs are present. When comparing the VBase2 IGLV reference sequences, a correlation between AL with IGLV references exhibiting especially low values was observed (**Figure 33 A**). More precisely, the IGLV6-57 reference (AL enriched) shows the lowest value of -0.751. The IGLV3-1 reference (AL enriched) shows a slightly higher value of -0.635, and the IGLV2-14 reference (AL and MM) has a value of -0.512. The IGLV1-44 reference sequence showed a comparable value of -0.492 and was detected to be the third most common IGLV subfamily in MM and only in 6 % of the AL cohort. The IGLV2-23 reference (MM only) shows the highest value (-0.452), followed by IGLV3-21 (-0.490), the most frequently detected IGLV subfamily in MM. However, further studies are needed to characterize an association in more detail.

Even though different IGLV segment reference sequences exhibit distinct pI values, no direct correlation was observed (**Figure 33 A**). However, the IGLV2-23 (MM only) reference shows the highest value with 6.74, followed by IGLV3-21 (5.60; MM enriched) and IGLV2-14 (5.55; AL and MM). The lowest value was noted for IGLV3-1 (4.52; AL enriched), IGLV6-57 (4.60;

AL enriched), and IGLV1-44 (4.60; MM enriched). Nevertheless, comparing the full-length IGLV2-14 and IGLV3-1 patient-derived AL and MM LC sequences, higher pI and  $\Delta$ pI and values were observed for the MM LC sequences. An analysis of urinary monoclonal LCs from patients with and without AL revealed a lower mean pI of 4.8 for AL-associated LCs compared to a pI of 6.2 for non-AL LCs – which is in concordance with the results of this study (Bellotti et al. 1990). AL IGLV6-57 sequences displayed the lowest value for the AL cohort and it was noticeable that the AL\_HK subgroup showed almost no deviation from the reference sequences. The pI, in combination with the pH of the environment, can have a strong influence on the net charge of a protein, in consequence, affects its solubility and aggregation propensity (Schein 1990; Schmittschmitt and Scholtz 2003). When neglecting factors such as protein folding and modifications, proteins are most stable and insoluble if the pH of the buffer solution is within 1.0 pH unit of the protein's pI. In a previously published own study (n = 10, mixed IGLV subfamilies, AL\_H, AL\_K, AL\_HTX), the analyzed AL LCs (IGLVJ) displayed a significant increase in pI compared to a reference sequence (Baur et al. 2022). However, this is not in concordance with the results of this larger study (n = 82, AL\_H, AL\_HK).

Overall, within this work different pI trends as well as differences in charged AAs were noted between AL and MM. This was also the case in the analysis regarding the AL organ tropism. In this context, it must be considered that in the case of AL, both, blood and tissue pH must be taken into account. So, the hypothesis can be postulated that not only mutations can increase the amyloidogenic potential but that these LCs must also be in the "right" environment to initially deposit as fibrils. These first fibrils could then, through a seeding effect, lead to the additional deposition of fibrils in other organs. However, further studies are needed to support these assumptions.

Since amyloid fibrils consist of many-stranded  $\beta$ -sheets, the AGG parameter, which indicates the tendency towards a  $\beta$ -sheet aggregation, was calculated. While the GRAVY score matches the IGLV family and disease association, this was not the case for the AGG parameter (**Figure 33 C**). When comparing the IGLV reference sequences, IGLV1-44 (20.9; MM enriched) and IGLV6-57 (55.4; AL enriched) show by far the lowest value, followed by IGLV2-23 (132.5; MM only) and IGLV2-14 (145.7; AL and MM). The IGLV3-21 (566.0; MM enriched) and IGLV3-1 (524.6; AL enriched) reference sequences displayed the highest values. When comparing actual patient-derived AL and MM IGLV2-14 and IGLV3-1 LCs, different trends were observed. Additionally, divergences regarding the AL organ tropism were noted: AL\_HK IGLV6-57 sequences displayed a lower value, and IGLV3-1 sequences a higher value than the respective AL\_H sequences. Thus, based on the results regarding the AGG parameter, no clear

trend or correlation was identified, and the results neither support nor reject the postulated hypotheses.

In the already addressed work by Belotti et al., a significant difference in the Mw of LCs was detected. They found LC fragments with a low Mw in the urine of 30 out of 34 AL patients and only 15 out of 51 non-AL patients (Bellotti et al. 1990). In this study, no significant difference was detected but the MM sequences also showed a slightly higher Mw compared to AL sequences of the corresponding IGLV subfamily. Interestingly, this contrasts with the Mw of the IGLV reference sequences. The IGLV1-44 (10016; MM enriched) reference displays the lowest Mw, followed by IGLV2-23 (10038, MM only) and IGLV3-21 (10073, MM enriched) (**Figure 33 D**). These three IGLV families showed an increased MM association. Further, IGLV3-1 (10093, AL enriched) and IGLV2-14 (10116, AL and MM) reference sequences show a higher Mw, but by far the highest value is detected for the IGLV6-57 reference (10643, AL enriched).

**Figure 33. Correlation of the percentage of the detected IGLV subfamilies in the AL amyloidosis and multiple myeloma cohort, with the (A) grand average of hydropathicity score, (B) Isoelectric point, (C) AGG parameter and (D) the molecular weight of the respective IGLV reference sequence.** AL = AL amyloidosis, MM = multiple myeloma, IGLV Ref = IGLV subfamily reference sequence, GRAVY = grand average of hydropathicity score, pI = isoelectric point, Mw = molecular weight

If postulating that different IGLV subfamilies differ in their inherent amyloidogenic potential, a possible relation between a low GRAVY score and a higher amyloidogenic potential can be assumed. As already mentioned, at first glance, an increased hydrophobicity contradicts the definition of insoluble amyloid fibrils. However, the GRAVY score only concerns the linear protein and neglects other factors influencing protein stability. Additionally, the results of this study are in concordance with the observations made by Belotti et al.: it was possible to detect a higher pI and molecular weight in MM than in AL patients. However, while the pI values partially match the IGLV subfamily/disease association, this was almost completely reversed in terms of the Mw. However, it also applies to the pI that only the linear protein is considered.

In conclusion, no additional general mechanisms were found that explain the divergent behavior of AL and MM LC based on the calculated biophysical parameters. Based on the results concerning the AL organ tropism and the pI of the LCs, it can be postulated that amyloidogenicity does not only emerge from the LCs itself but that the tissue environment could also be a decisive factor.

### **4.3 Influence of a Potential Heavy Chain Binding Partner or dFLC >180 mg/L**

In order to obtain even deeper insights into the potential pathogenic mechanisms in AL, the sequences were stratified with respect to two additional parameters. In the following chapter, the results of this work are placed in the context of the underlying hypotheses and discussed in more detail.

#### **4.3.1 Potential Heavy Chain Binding Partner**

One potential hypothesis for AL concerns the presence or absence of a potential clonal HC-binding partner (Bochtler et al. 2008). This is further supported by the fact that the CA t(11;14) is not only associated with a loss of the HC in 80 % of the cases but also more frequently associated with AL than MM (Bochtler et al. 2008; Bochtler et al. 2018). The results of this study suggest that charges and small AAs have a decisive role in the differentiation between AL and MM LCs. Further, it is assumed that each IGLV subfamily should be considered individually and may have its own pathological mechanisms. This is particularly evident when stratifying for the absence of a clonal HC.

To bring IGLV2-14 into focus, the AL HC subgroup showed a higher IGLV mutation count and comprised all LCs with a mutation in the IGLC segment. Further, differences in charge and small AAs were noted between the AL subgroups. Only the AL HC sequences showed an H41N

mutation and additional prolines in the linker region. However, the biophysical parameters showed a striking difference. Here, the AL HC sequences showed a significantly higher AGG parameter than the AL no HC sequences. This is complemented by the fact that the AL HC sequences further showed a higher pI than the AL no HC subgroup

These phenomena were also partially noted for the IGLV3-1 subfamily. Although the differences were not as prominent, all IGLV3-1 AL sequences with a mutation in the IGLC segment belonged to the AL HC subgroup. Interestingly, the IGLV2-14 and IGLV3-1 AL HC sequences presented a higher mutation frequency or count in the FR3 than the respective other subgroup. It was also noticeable that the AL IGLV3-1 CDR3 region showed a difference between these subgroups: the AL HC sequences showed a higher proportion of alanine and the AL no HC sequences of glycine. Both AAs are small and no obvious discriminating aspect can be mentioned – thus, the possible effects or consequences need to be further investigated in protein analyses.

An additional hypothesis can be formed based on these results: In the presence of a potential clonal HC binding partner, a misfit between HC and LCs might influence the excess of free LCs. This can be supported by an increased mutation count in the IGLV segment, especially in FR3, and the IGLC segment as well as certain sequence characteristics. In the context of AL, there might be a positive selection for LCs that exhibit a higher aggregation tendency or a pI close to the physiological pH of the blood and might therefore be insoluble within the patient's bloodstream.

#### 4.3.2 Influence of a dFLC > or < 180mg/L

As expected, the detected differences and resulting hypothesis do not apply to all IGLV subfamilies. For IGLV6-57, AL\_H no HC sequences showed a higher IGLJ mutation frequency, and all IGLC-mutated sequences belonged to this subgroup. However, IGLV6-57 AL sequences showed the most prominent difference when stratifying for the dFLC. This stratification approach was chosen to investigate if the size and malignancy of the B cell tumor correlate with the characteristics of the respective LCs. Although clinical risk stratifications apply different thresholds for AL and MM patients, this study cut-off was set at >180 mg/L. Here, the IGLV6-57 subfamily stood out, despite mutation number and frequency showing no significant differences between the AL dFLC subgroups.

IGLV6-57 AL < dFLC sequences frequently showed an insertion of charged AAs in the CDR2. Further, the Mw of the LCs showed a notable difference. In this context, the AL > dFLC subgroups displayed a higher Mw – not only in the IGLV6-57 but also in the IGLV2-14 subfamily. This is of special interest when considering that a larger Mw was also detected for MM compared to AL sequences. Most AL patients present with an underlying MGUS with low tumor burden and less frequently with underlying MM and a respective higher tumor load. If postulating that a higher tumor burden is associated with a higher Mw of the disease-associated LCs, this also seems reasonable for AL and a dFLC >180 mg/L. However, the underlying mechanism and consequence remain unclear.

#### 4.4 Prediction of Amyloidogenicity

The detected differences between AL and MM, as well as the subgroup analyses, can not only be used to further investigate the pathogenic mechanisms but also be brought into a more clinical context: toxicity prediction and risk stratification. A clinical risk stratification tool that could predict a patient's risk for developing AL from MGUS, SMM, or MM is highly sought-after. Identifying high-risk patients would allow monitoring strategies, early diagnosis, and early treatment and ultimately, prevent end-organ damage.

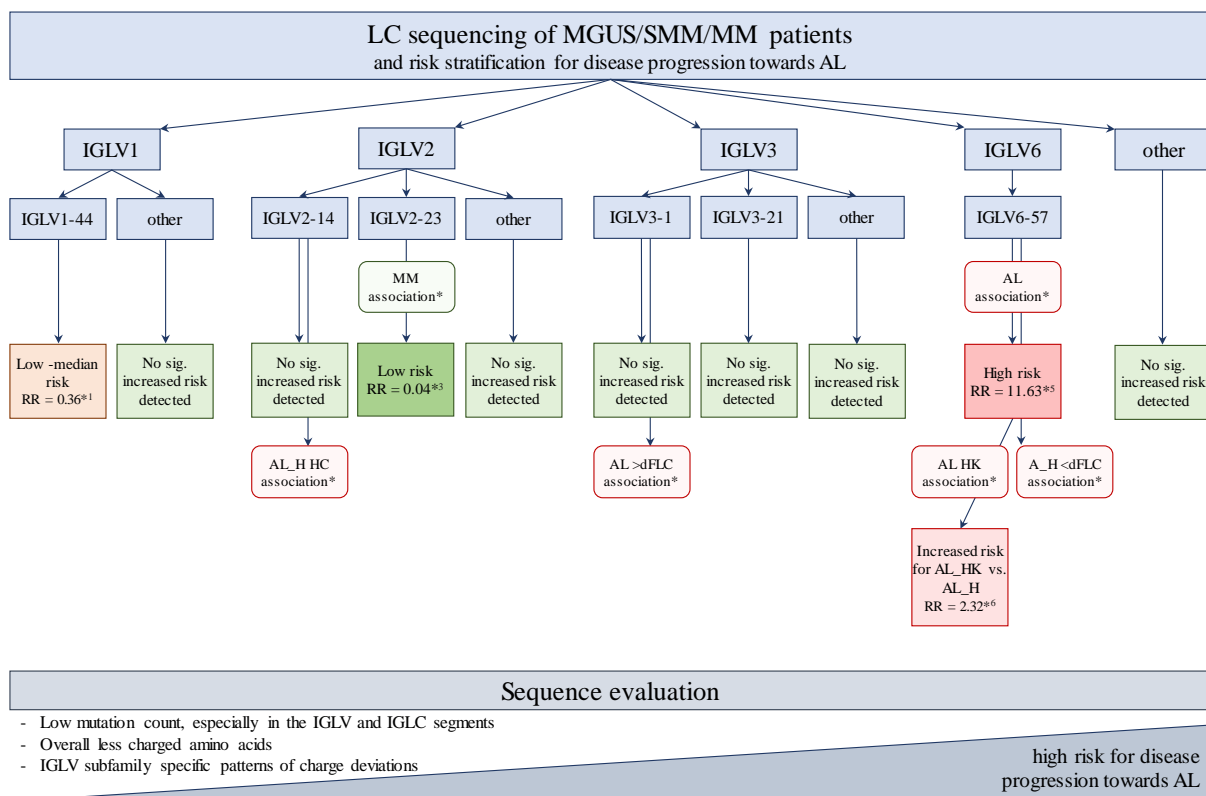

In 2021, a web-based tool for toxicity prediction of lambda LCs based on somatic mutations was established: LICTOR. The underlying machine learning analysis is said to have an 80 % accuracy in LC classification (Garofalo et al. 2021). When applying this tool to the IGLV2-14 subfamily, seven out of eight MM sequences and nine out of fourteen AL sequences were indicated as toxic. In two AL cases, the tool failed and provided no evaluation. So, when considering only the IGLV2-14 AL sequences, the accuracy is only 64 %. The overall accuracy is down to 41 % when also including the IGLV2-14 MM sequences. However, it is a newly established application, and the prediction will be improving over time, so it will potentially become a helpful tool.

Within this work, a different approach for risk stratification is needed since no mutation or mutations allowed a distinct differentiation of AL and MM LCs. In this context, the IGLV subfamily usage may play a decisive role (**Figure 34**). The findings of this study are well in line with these of previously published ones and suggest a higher amyloidogenic potential for some IGLV subfamilies. Further, the IGLV subfamilies appear to be associated with distinct organ involvement, high dFLC, or the presence of a potential HC-binding partner.

So, based on the results of this study, a new model for risk stratification can be suggested. In this context, IGLV6-57 and IGLV2-23 can serve as a model for further explanation. MGUS

patients with IGLV6-57-assigned LCs have an increased risk for disease progression towards AL: relative risk of 11.63 ( $p = 0.015$ ). This is hypothesized since IGLV6-57 was significantly associated with AL. Vice versa, MGUS patients with an IGLV2-23 assigned LC should have a much lower risk for progression towards AL: relative risk 0.04 ( $p = 0.023$ ). This is stated because IGLV2-23 was found exclusively in the MM cohort.

Further, not only the IGLV subfamilies presented variation but also an influence of a potential HC binding partner or the dFLC can be detected. For example, IGLV3-1 was frequently detected in the MM and AL cohort but also a significant AL > dFLC association was noted. So, IGLV subfamilies frequently detected in both cohorts must be considered in more detailed sequence analyses. More generally, an increased risk for the development of AL may be indicated by a low mutation count in the IGLV and IGLC segment, as well as fewer charged AAs.

**Figure 34. Risk stratification of monoclonal gammopathy of undefined significance/smoldering multiple myeloma/multiple myeloma patients for the progression towards AL amyloidosis based on light chain sequencing results.** The scheme was developed based on the data of this work and specifically refers to the detected differences in the IGLV subfamily distribution between AL amyloidosis patients with dominant heart involvement, AL amyloidosis patients with dominant heart and kidney involvement, and multiple myeloma patients. MGUS = monoclonal gammopathy of undefined significance, SMM = smoldering multiple myeloma, MM = multiple myeloma AL = AL amyloidosis, LC = light chain, HC = heavy chain; RR = relative risk. \* =  $p \leq 0.05$ . The relative risk was calculated using the web-based MedCalc relative risk tool. P-values of the IGLV subfamily associations are mentioned in chapter 3.3. <sup>1</sup> $p = 0.053$ , <sup>2</sup> $p = 0.054$ , <sup>3</sup> $p = 0.023$ , <sup>4</sup> $p = 0.047$ , <sup>5</sup> $p = 0.015$ , <sup>6</sup> $p = 0.036$ , <sup>7</sup> $p = 0.008$ .

#### 4.5 Outlook

Among the aspects that should be studied in more detail, two thematic areas can be distinguished. The first area concerns the biology of AL and the disease underlying pathological mechanisms. Here, it is still not evident why some IGLV subfamilies are more associated with AL and others are not. To address this question, a more holistic view of the sequence and protein level should be approached. In this context, AL, MM, and even reference sequences should be compared systematically. These comparisons should provide necessary information to understand especially the IGLV subfamily distribution and the hypothesized divergent inherent amyloidogenic potential. In more detail, which biophysical parameters and sequence characteristics or modifications are ultimately decisive for LCs to form fibrils or which other factors need to be considered more intensively.

The landmark for this work has already been established based on an AL LC of the IGLV2-14 subfamily. This work examined each individual mutation site regarding its influence on fibril formation in vitro, and indeed, one mutation was crucial for fibril formation (Kazman et al. 2020).

Besides the IGLV subfamily usage, the hypothesis that a misfit between HC and LC influences the excess of free LCs still needs to be analyzed in more detail (Bochtler et al. 2008). This analysis should concern the sequence and protein level. Addressing the protein level, nuclear magnetic resonance experiments could provide information about the interaction between these two proteins in more detail. On top of this, bioinformatics models/predictions could be useful to compare references as well as MM and AL HC and LC pairs.

This study was limited by analyzing a not completely representative AL cohort; nevertheless, comparing AL\_H and AL\_HK sequences provided new insights. To further investigate the organ tropism in AL, the results of this work should be merged with the results of the work of Sarah Schreiner, which analyzes AL\_K and AL\_D sequences. In the context of the postulated hypothesis that the tissue environment may play a crucial role, further bioinformatic or protein analyses are necessary. Here, investigations of the different tissues themselves and different amyloid-associated proteins are needed (Gottwald and Röcken 2021). Beyond the LCs, it should be analyzed which pathways or even known plasma cell factor-associated factors/proteins show a deviation between AL and MM and between the AL organ involvements.

The second thematic aspect concerns risk stratification for a progression towards AL. In the context of this study, an approach based on the IGLV subfamily distribution and clinical parameters was chosen. However, not only sample sets covering a disease progression but also larger cohorts are necessary. These additional samples are also necessary to further investigate the detected sequence characteristics and differences between AL and MM and to establish them as potential biomarkers. Through this work, a preliminary model could be postulated, which, however, still needs to be expanded and verified through additional analyses.

## 5 Summary

Immunoglobulins and their component light chains are essential parts of the human immune system. Even though, in the context of an AL amyloidosis disease, light chains can be pathogenic. This pathogenicity arises from at least one malignant plasma cell, which infiltrates the bone marrow and produces an excess of free light chains – which misfold and ultimately deposit as fibrils in the extracellular space. Why and how these naturally soluble light chains transit into fibrils is still unknown.

One research approach relies on the natural function of the light chains themselves: antigen recognition and underlying sequence diversity. The analysis of this sequence diversity and corresponding mutations may allow making inferences about potential pathogenic mechanisms in AL amyloidosis. Nevertheless, a control group is needed to draw distinct conclusions. Here, light chains from the related plasma cell disorder multiple myeloma, which do not form fibrils, offer a suitable option. This work compared full-length lambda light chain sequences from 82 AL amyloidosis and 52 multiple myeloma patients and revealed several striking aspects – such as, a significant association between IGLV6-57 and AL amyloidosis as well as between IGLV2-23 and multiple myeloma. Overall, the results of this work are well in line with previously published studies and strengthen the assumption that IGLV subfamilies present a difference in their amyloidogenic potential. Intuitively, mutations may alter this inherent amyloidogenic potential. In the context of this work, mutation analyses showed that not the quantity but rather the distinct exchange pattern and location might be crucial. This hypothesis rests upon the findings that the multiple myeloma sequences always displayed a significantly higher mutation count than the respective AL amyloidosis sequences and the detection of different exchange patterns. In more detail, these patterns mostly concerned charged amino acids and even differed between the analyzed IGLV subfamilies. Therefore, individual pathological sequence-based mechanisms for each IGLV subfamily are hypothesized.

In addition to the characteristic of light chain fibril formation, AL amyloidosis patients often show a distinct organ tropism. To further analyze this aspect, the AL amyloidosis patients were stratified accordingly beforehand. In the end, this study included 61 patients with a dominant heart and 21 patients with a heart and kidney involvement. When comparing these subgroups, it was possible to detect differences concerning the IGLV subfamily assignment, mutation counts, and again most prominently, charged amino acids. In the context of charged amino acids, the IGLV6-57 assigned sequences stood out. Here, it was possible to detect diverging patterns between the two AL amyloidosis subgroups in several regions. Taken together, these results suggest that not exclusively the light chains themselves, but also the tissue environment

might influence their amyloidogenic potential which are mirrored in certain sequence characteristics.

Besides the already mentioned high levels of free light chains, AL amyloidosis patients frequently display a loss of the clonal heavy chain. To further investigate these parameters and to find out if they reflect in certain light chain sequence characteristics, the AL amyloidosis and multiple myeloma cohort were accordingly stratified. Addressing the level of free light chains, the most prominent difference concerned the molecular weight of the light chains. IGLV6-57 and IGLV2-14 AL amyloidosis sequences from patients with a high level of free light chains displayed a higher molecular weight than the other subgroup. The second analysis concerning the presence or absence of a clonal heavy chain revealed an increased mutation count in the IGLV and the IGLC segment of light chains with potential heavy chain binding partners. These results led to the hypothesis that mismatched heavy chains and light chains might influence the excess of free light chains. In this context, there might also be a positive selection for light chains that exhibit a higher aggregation tendency and isoelectric point close to the physiological pH of the blood – which would render them insoluble within the patient's bloodstream.

In conclusion, the results of this study lead to several intertwining hypotheses concerning the pathogenic mechanisms in AL amyloidosis: *Certain IGLV subfamilies innately present with favorable properties for amyloid formation. Here, individual pathological sequence-based mechanisms, which frequently involve alterations of charged amino acids, can be assumed. Further, not only the light chains themselves but also external factors, like the tissue environment and a potential clonal heavy chain binding partner, might influence their amyloidogenicity. In this context, there might also be a positive selection for light chains which exhibit favorable characteristics like an increased aggregation tendency or a favorable isoelectric point.*

Besides the biological questions concerning the pathogenic mechanisms, there is an urgent need for a screening option for patients with a monoclonal gammopathy of undefined significance on the clinical/medical side. Identifying patients at high risk for disease progression towards AL amyloidosis would possibly prevent end-organ damage due to earlier diagnosis. Based on the results of this work, a risk stratification mainly based on the IGLV subfamily usage was established. Keeping the previously mentioned IGLV associations in mind, it is reasonable that the highest significant relative risk, 11.63, was calculated for IGLV6-57. In contrast, the lowest significant relative risk, 0.04, was detected for IGLV2-23.

In summary, this work contributes to resolving the pathogenic mechanisms of AL amyloidosis and provides a starting point for clinical risk assessment based on light chain sequencing.

## 6 Zusammenfassung

Immunglobuline und als ihr Bestandteil somit auch Leichtketten, sind ein wichtiger Teil des menschlichen Immunsystems. Im Rahmen einer AL Amyloidose Erkrankung können Leichtketten jedoch auch einen pathogenen Effekt haben. Dieser resultiert daraus, dass mindestens eine maligne Plasmazelle das Knochenmark infiltriert und einen Überschuss an Leichtketten produziert. Anschließend kommt es zur Fehlfaltung dieser Leichtketten, die sich schlussendlich in Form von Fibrillen im extrazellulären Raum ablagern. Warum und wie genau diese Leichtkettentransition stattfindet, ist jedoch noch nicht vollständig verstanden.

Ein Ansatz, um diesen Mechanismus näher zu untersuchen, basiert auf der natürlichen Funktion der Leichtketten: der Erkennung von Antigenen und der damit einhergehenden Sequenz Diversität. Durch eine Analyse dieser Diversität und den zugrunde liegenden Mutationen sollten Rückschlüsse auf die pathogenen Mechanismen gezogen werden können. Hierbei ist eine Kontrollgruppe essenziell. Die beste Option bieten Patienten und Patientinnen mit Multiplem Myelom – hier werden Leichtketten zwar übermäßig produziert, bilden aber keine Fibrillen.

Im Rahmen dieser Arbeit wurden die kompletten lambda Leichtketten Sequenzen von 82 AL Amyloidose und 52 Multiplem Myelom Patienten und Patientinnen miteinander verglichen. Hierbei konnte unter anderem eine signifikante Assoziation zwischen IGLV6-57 und der AL Amyloidose sowie IGLV2-23 und dem Multiplem Myelom detektiert werden. In Einklang mit bereits publizierten Daten kann somit postuliert werden, dass die IGLV Subfamilien ein unterschiedliches amyloidogenes Potenzial aufweisen. Es ist naheliegend, dass dieses amyloidogene Potenzial durch Mutationen beeinflusst werden kann. In den Mutationsanalysen zeigte sich jedoch, dass nicht die Anzahl, sondern eher der spezifische Austausch und die Region ausschlaggebend sein könnten. Diese Annahme basiert darauf, dass die Multiple Myelom Sequenzen eine signifikant höhere Anzahl von Mutationen aufwiesen und spezifische Mutationsmuster detektiert werden konnten. Diese Mutationsmuster betrafen im Besonderen geladene Aminosäuren und unterschieden sich zwischen den analysierten IGLV Subfamilien. Daher kann postuliert werden, dass es zusätzlich individuelle sequenzbasierte pathogene Mechanismen für die einzelnen IGLV Subfamilien gibt.

Ein weiteres charakteristisches Merkmal der AL Amyloidose ist der spezifische Organtropismus. Um dieses Phänomen näher zu untersuchen, wurden die Patienten und Patientinnen vor dem Beginn dieser Studie entsprechend stratifiziert, sodass die AL Amyloidose Kohorte 61 Fälle mit dominantem Herzbefall und 21 Fälle mit Herz- und Nierenbefall umfasste. Auch in diesem Vergleich konnten Unterschiede in Bezug auf die IGLV

Subfamilien und Mutationen detektiert werden. Herausstechend waren erneut Unterschiede in Bezug auf geladene Aminosäuren und insbesondere die IGLV6-57 Subfamilie. Diese Ergebnisse führten zu der Hypothese, dass nicht nur die Leichtketten selbst, sondern auch externe Faktoren wie das umliegende Gewebe einen Einfluss auf die Amyloidogenität haben und sich in spezifischen Sequenzcharakteristika wiederfinden.

Neben dem erhöhten Wert freier Leichtketten zeigen AL Amyloidose Patienten und Patientinnen ebenfalls häufig einen Verlust der klonalen schweren Kette. Um zu untersuchen, ob diese beiden Parameter sich auch in den Eigenschaften der Leichtketten widerspiegeln, wurden die Kohorten entsprechend stratifiziert. Auffallend war, dass IGLV2-14 und IGLV6-57 AL Amyloidose Sequenzen, die mit einem hohen Wert an freien Leichtketten assoziiert waren, auch ein höheres Molekulargewicht zeigten. In der zweiten Analyse bezüglich der An- oder Abwesenheit einer schweren Kette zeigten die Leichtketten Sequenzen mit potenziellm Bindungspartner mehr Mutationen im IGLV und IGLC Segment. Diese Ergebnisse führten insgesamt zu der Hypothese, dass der Überfluss an freien Leichtketten potenziell durch nicht passende schwere Ketten beeinflusst wird. Zusätzlich kann eine positive Selektion für Leichtketten, die eine erhöhte Aggregationstendenz und einen isoelektrischen Punkt nahe dem des Blutes aufweisen, angenommen werden.

Die auf dieser Arbeit basierenden Hypothesen werden im Folgenden kurz zusammengefasst: *Es gibt IGLV Subfamilien, die ein erhöhtes primäres amyloidogenes Potenzial aufweisen. In diesem Kontext können individuelle sequenzbasierte pathogene Mechanismen angenommen werden, die im Besonderen geladene Aminosäuren involvieren. Es kann ebenfalls davon ausgegangen werden, dass externe Faktoren wie das umliegende Gewebe oder auch ein potenzieller Bindungspartner einen Einfluss auf die Amyloidogenität haben. Hierbei ist eine zugrunde liegend positive Selektion für Leichtketten mit vorteilhaften Eigenschaften denkbar.*

Aus klinischer Perspektive besteht die dringende Notwendigkeit für eine Screening-Option für Patienten und Patientinnen mit einer monoklonalen Gammopathie unklarer Signifikanz hinsichtlich ihres Risikos, eine AL Amyloidose zu entwickeln. Dadurch könnten drastische Organschäden durch eine frühere Diagnose verhindert werden. Diese Arbeit nutzte im Besonderen die IGLV Subfamilien Verteilung für eine Risikoeinschätzung. Darauf basierend konnte für IGLV6-57 das höchste signifikante relative Risiko mit 11,63 und für IGLV2-23 das niedrigste signifikante relative Risiko mit 0,04 berechnet werden.

Zusammenfassend trägt diese Arbeit dazu bei, die pathogenen Mechanismen in der AL Amyloidose weiter zu charakterisieren und liefert einen Ansatzpunkt für eine Risikobewertung im klinischen Kontext.

## **8 Own Contribution to Data Collection, Analysis and Publications**

This work was conducted as part of the research consortium FOR2969 entitled "Mechanisms of antibody light chain misfolding in systemic AL amyloidosis".

In the course of clinical diagnostics, bone marrow aspirates of AL amyloidosis patients were obtained by physicians. These bone marrow aspirates were processed in equal parts by Sarah Schreiner and myself – regardless a kappa or lambda LC or the organ involvement. In general, stratification for the organ tropism was carried out by Prof. Dr. Ute Hegenbart.

Starting from GTC138<sup>+</sup> cell pellets, the sample processing and targeted amplification of the lambda LCs of AL\_H and AL\_HK patients were performed mainly by myself (Sarah Schreiner: AL\_K and AL\_D patients). Twenty-two AL\_H and AL\_HK patients underwent bone marrow aspiration prior to the start of this study. These patients were also included in this study since leftover sample material was available in the biobank.

The underlying PCR method for the amplification of full-length lambda LCs was adapted, extended, and verified entirely by myself. In principle, this method and some forwards oligonucleotides were extracted from a published protocol by Dr. Stefanie Huhn. The cell lines initially used as PCR templates were provided by Dr. Mohammed H.S. Awwad.

The extraction and evaluation of the AL\_H and AL\_HK sequences and the extraction and analysis of the clinical parameters from the patient reports were also carried out entirely by myself. These two aspects together constitute the main part of this work.

The additional NGS AL IGLV3-21 experiments were planned by myself and subsequently performed together with Sarah Schreiner and Dr. Philipp Reichert. The bioinformatic processing and extraction of the LC sequences were carried out by Sarah Schreiner. The subsequent detailed sequence analysis of the AL\_H samples was carried out exclusively by myself and followed the protocols described in chapters 2.9.3 to 2.9.7 (including translation).

The lambda MM LC sequences were generated using a bulk RNA sequencing approach, which was not part of this work. The subsequent bioinformatic analysis and extraction of the LCs were also not carried out as part of this work, but rather by Dr. Alexandra M. Poos. In addition to the sequences, the clinical parameters were also provided by the GMMG study group. In the framework of this work, the translation and analysis of the lambda MM LC sequences, as described in chapters 2.9.3 to 2.9.7, was exclusively performed by myself. Additionally, I extracted and analyzed the parameters necessary for a comparison from the information provided.

In summary, the lambda MM as well as AL\_H and AL\_HK LC sequences and associated clinical parameters were analyzed in detail and compared exclusively by myself. The subsequent evaluation, visualization, statistical analysis as well as interpretation of the data in the context of the discussion was also carried out entirely by myself.

**Partial results of the present work have been pre-published in the following papers:**

\*authors contributed equally to this work.

**Publication 1** included a preliminary dataset consisting of lambda LC sequences from AL\_H, AL\_HK, and AL\_K patients. The clinical parameters of the AL\_H and AL\_HK patients are part of the analysis in chapter 3.1. The analysis of the IGLV families and subfamilies is part of chapter 3.3.1, and the data for the analysis of the complete LCs are included in chapters 3.3.2 and 3.3.3. The IGLV subfamily distribution of AL\_K LC sequences, analyzed by Sarah Schreiner, was used for comparison in chapter 4.2.1. My contribution to the publication included the generation and analysis of the AL\_H and AL\_HK sequences, as well as the compilation of the corresponding patient data. The clinical parameter and sequence data concerning AL\_K patients were analyzed by Sarah Schreiner. I performed the merger and visualization of the complete dataset. Additionally, the manuscript draft with the introduction, material methods, result, and discussion part were written by myself.

**Publication 2** was carried out in cooperation with a research group in Ulm under the leadership of Prof. Markus Fändrich and Dr. Christian Haupt. The involved PhD student Julian Baur and I share the first authorship on this publication. The work includes sequences of AL\_HTX

(n = 2), AL\_H (n = 6), and AL\_K (n = 2) patients, which constituted the essential basis for further conducted investigations. My contribution to this work was the generation and analysis of the AL\_H sequences and the collection of clinical data. The previously published sequences of the AL\_HTX sequences were also reanalyzed and put into context by myself. The patient data of the AL\_H sequences are included in the analysis in chapter 3.1. The sequence analyses of the six AL\_H LCs are included in the corresponding chapters for the respective IGLV subfamily (chapters 3.4, 3.9.1, 3.9.2, 3.9.7). The additional mass spectrometry experiments are included in the discussion under chapter 4.1. Additionally, I have written the corresponding material methods part, the results part as well as the part of the discussion of the manuscript that concerns the sequence data.

**Publication 3** included a preliminary dataset consisting of IGLV2-14 LC sequences from AL\_H, AL\_HK, AL\_K, and MM patients. The respective AL\_H, AL\_HK, and AL\_K sequences were already part of **publication 1**. My contribution to this work was the generation and analysis of the AL\_H and AL\_HK sequences and collection of the clinical data as well as the sequence analysis of the MM LCs. The AL\_K sequences were generated and analyzed by Sarah Schreiner, who also collected and analyzed the clinical data of the AL\_K patients. The merger, visualization, and statistical analysis of the complete dataset was also performed by myself. Additionally, I wrote the manuscript draft including the introduction, material methods, result and discussion part.

#### **Further publications with own contributions:**

4. Rademaker, L., Karimi-Farsijani, S., Andreotti, G., Baur, J., Neumann, M., Schreiner, S., Berghaus, N., Motika, R., Haupt, C., Walther, P., Schmidt, V., Huhn, S., Hegenbart, U., Schönland, S. O., Wiese, S., Read, C., Schmidt, M. and Fändrich, M. (2021). **Role of mutations and post-translational modifications in systemic AL amyloidosis studied by cryo-EM.** *Nature Commun* 12(1), 6434, doi:10.1038/s41467-021-26553-9.
5. Schreiner, S., Berghaus, N., Poos, A. M., Raab, M. S., Besemer, B., Fenk, R., Goldschmidt, H., Mai, E. K., Müller-Tidow, C., Weinhold, N., Hegenbart, U., Huhn, S. and Schönland S. O. (2023). **Sequence diversity of kappa light chains from patients with AL amyloidosis and multiple myeloma.** (under Review, Amyloid)

**Publication 4** is a cryo-EM analysis of a patient-derived AL amyloid fibril. Within this work, the newly generated fibril and associated LC sequence were compared with other known sequences of cryo-EM resolved fibrils. My part in this work was the detailed sequence analysis

of the individual LC sequences and a consequential comparison. Furthermore, I was also involved in the editing of the manuscript.

**Publication 5** includes the analysis of 41 AL amyloidosis and 83 MM kappa LC sequences. The complete cohorts were analyzed regarding the IGKV and IGKJ gene usage and the AL cohort also in context of the organ involvement. Further, the AL and MM LC sequences assigned to IGKV1/D-33 were analyzed in terms of mutations and biochemical properties. I was involved in processing the underlying AL bone marrow samples and editing of the manuscript.

## Appendix

### Appendix Material and Methods

**Supplementary Information Table 1. Inclusion and exclusion criteria for the GMMG-HD6 trial.** Retrieved from (Salwender et al. 2019).  <b>RoboSep</b>		SOP zur Roboterunterstützten CD138+ Sortierung von Probenmaterial nach dem StemCell Protokoll
<b>1. CD138+ Sortierung mit RoboSep</b>		
Schritt	Protokoll	Check
0	<b>RoboSep Puffer</b> auf Raumtemperatur bringen	
Pre-FACS	1 Aliquot 100µl Vollknochenmark unverdünnt (50µl pro Falcon vor PBS)	
<b>Zell-Zählung gesamt</b>	Counter: 10µl Trypanblau (0,4%) und 10µl Zellsuspension mischen (1:2) *** bei sehr viel zu erwartenden Material 1:10 zählen (10µl Zellen + 90µl Trypb.) Mikroskop: 10 µl Zellsuspension und 90 µl <b>Türkische Lösung</b> mischen (1:10) *** bei sehr viel zu erwartenden Material 1:50 zählen (1µl Zellen + 49µl Türk.)	
	10µl gefärbte Mischung in jeweilige Zählkammer geben	
	Mit dem Mikroskop auszählen und berechnen <small>T:\text01\MED5-Labor\Weinhold\Formel zum Berechnen der Gesamtzellzahl (wenn mit Neubauer Kammern gezählt wurde).xlsx</small> Counter: $Zellzahl \cdot ml \cdot (falls\ verdünnt\ Faktor)$ Mikroskop: $Zellzahl \cdot Verdünnung \cdot (1e4) \cdot ml\ Probe$	
	Ergebnis in FACS-Liste eintragen	
3	Während dem Zählen Zellsuspension bereits abzentrifugieren, 1.500 rpm/g für 5 Minuten	
4	Überstand verwerfen	
5	Zellpellet je nach Zellzahl in mind. 1ml bis max. 3,99ml <b>1xPBS/EDTA/FCS</b> lösen und in ein 14ml Tube überführen *** ➤ Optimum liegt bei $1 \cdot 10^8$ Zellen/ml *** wenn das Pellet sehr groß ist oder viel PBS Puffer Rest im Tube verbleibt muss das Volumen des RoboSep Puffers um das Pellet Volumen reduziert werden	
6	RoboSep anschalten	
7	Benutzerprofil (Lab. Huhn) und Protokoll (Human CD138 WB and BM Positive Selection II 17887) auswählen, dafür auf Select Protocol klicken und mit Pfeiltaste bestätigen	
8	Probenvolumen eingeben und mit Enter bestätigen	
9	Bei mehreren Proben Schritt 7 und 8 wiederholen	
10	Die Quadranten des Karussells nacheinander beladen <small>(Beladungsschema auf Bildschirm)</small> ➤ Pipettierarm des Roboters mit 1-2 Tropfen aus Tropfflasche säubern ➤ Überprüfen, ob <b>Wasser- und Pufferflasche</b> voll genug sind*** ➤ <b>Beads</b> für etwa 30 Sekunden vortexen ➤ <b>Cocktail</b> leicht schwenken ➤ Darauf achten, dass alle Tubes beschriftet und Deckel entfernt sind ➤ Spitzen Box fest in den Quadranten drücken Um nächsten Quadranten zu beladen auf Pfeiltaste drücken. ***	
	File: <a href="#">SOP_RoboSep_08_2022</a> Version: <a href="#">Jan-Stefanie Huhn, Stefanie Huhn, stefanie.huhn@med.uni-wuerzburg.de</a> last changed: <a href="#">15.08.2022</a> created: <a href="#">3</a>	©\Med_5\MedBz_Huhn_Reicher\SOPs\SOP_RoboSep_08_2022.docx Seite 1 von 2

 <b>RoboSep</b>		SOP zur Roboterunterstützten CD138+ Sortierung von Probenmaterial nach dem StemCell Protokoll
*** Reagenzien höchstens 3x wieder auffüllen, nur mit gleicher LOD Nummer auffüllen *** bei gleichem Protokoll für mehrere Proben die Reagenzien nur in den ersten Quadranten gestellt werden, in den weiteren Quadranten sind nur Probe, Tubes und Tip Racks nötig		
11	Wenn alle Quadranten vollständig beladen sind, auf Pfeiltaste (Run) drücken	
12	Roboter überprüft Barcodes der Reagenzien	
13	Nach dem Lauf die Auswerttaste drücken und Positiv- und Negativfraktion entnehmen	
14	Pellet der „+“ Fraktion in 5ml <b>1xPBS/EDTA/FCS</b> lösen und den Rand des Tubes gut abspülen und über Filter 1x Waschen	
15	Reagenzien (Beads, Cocktail und Puffer) wieder in Kit in Kühlschrank stellen, Waste und Tip Rack verwerfen	
16	Um RoboSep auszuschalten zurück zum Home screen und auf Shut down drücken ➤ Warten bis RoboSep in seiner endgültigen Position steht, <b>erst dann mit dem Klickschalter ausschalten</b>	
<b>Zell-Zählung</b>	10 µl Zellsuspension die „+“ Fraktion und 90 µl <b>Trypan Blau</b> mischen (1:10) *** bei sehr wenig zu erwartenden Material 1:2 zählen (10µl Zellen + 10µl Tryp.) 5 µl Zellsuspension die „-“ Fraktion und 95 µl <b>Trypan Blau</b> mischen (1:20) *** bei sehr viel zu erwartenden Material 1:50 zählen (1µl Zellen + 49µl Tryp.)	
	jeweils 10µl gefärbte Mischung in ein Fach einer Neubauer Einmal-Zählkammer geben Mit dem Mikroskop auszählen und berechnen <small>T:\text01\MED5-Labor\Weinhold\Formel zum Berechnen der Gesamtzellzahl (wenn mit Neubauer Kammern gezählt wurde).xlsx</small>	
<b>Positiv und Negativ Fraktion</b>	„+“ Fraktion 1:10 (10µl Zellen mit 90µl TB): Counter: $Zellzahl \cdot ml \cdot (falls\ verdünnt\ Faktor)$ Mikroskop: $Zellzahl \cdot Verdünnung \cdot (1e4) \cdot ml\ Probe$	
	„-“ Fraktion 1:20 (5µl Zellen mit 95µl TB): Counter: $Zellzahl \cdot ml \cdot (falls\ verdünnt\ Faktor)$ Mikroskop: $Zellzahl \cdot Verdünnung \cdot (1e4) \cdot ml\ Probe$	
18	30ml „-“ Fraktion zum Pellet zentrifugieren 1.500rpm/g 10min. in <b>2ml 1xPBS/EDTA/FCS resuspendieren</b>	Wenn in Ausnahmefällen aus der Positivfraktion einzig ein GTC Pellet zu erstellen ist, kann diese Probe analog zur Negativfraktion weiterverarbeitet werden!
19	Mit Cytospin Protokoll und Studien-SOPs fortfahren <b>Achtung:</b> Ausrechnen der „+“ Fraktion Konzentrationen für Aliquots! Zellzahl pro ml in 2ml!	
	File: <a href="#">SOP_RoboSep_08_2022</a> Version: <a href="#">Jan-Stefanie Huhn, Stefanie Huhn, stefanie.huhn@med.uni-wuerzburg.de</a> last changed: <a href="#">15.08.2022</a> created: <a href="#">3</a>	©\Med_5\MedBz_Huhn_Reicher\SOPs\SOP_RoboSep_08_2022.docx Seite 2 von 2

	<b>Countess</b>	SOP zum Zählen der Zellzahl von Proben mittels Countess Cell-Counter
---	-----------------	--

## 1. Zählen der Zellzahl mittels Countess Cell-Counter

Schritt	Protokoll
0	Counter ist in der Regel eingeschaltet, durch Tippen auf Bildschirm testen; sonst Einschaltknopf am Gerät hinten bedienen
<b>CAVE!</b>	<b>Nur Gesamtzellzahl und "-" Fraktion</b> am Counter zählen, "+" Fraktion wird manuell am Mikroskop gezählt <i>siehe SOP zum Sortieren der KM-Proben "Zellzählung Positiv Fraktion"</i>
Mo. u.n.B.	Countess test beads 1:2 mit Trypanblau mischen, 10µl in "Countess Cell" Zählkammer pipettieren; Ergebnis sollte sein: $1 \times 10^6 / \text{mL} \pm 10\%$
Vorbereiten der Probe	10µl Trypanblau (0,4%) und 10µl Zellsuspension mischen (1:2)  *** bei sehr großem Pellet eine höhere Verdünnung wählen (z.B. 1:10 [10µl Zellen + 90µl TB] oder höher); Der optimale Messbereich liegt bei $1 \times 10^5 - 4 \times 10^6$ Zellen/mL (Anzeige am Counter /mL (Anzeige am Counter))  10µl Mix in "Countess Cell" Zählkammer geben (ca. 30sek setzen lassen) Zählkammer in den Counter schieben; korrekte Position ist erreicht, wenn man einen soften Klick hört
Zellzählung	In der linken oberen Ecke ist das laufende Profil (gängig ist: "Standard") zu sehen; sollte dies nicht der Fall sein, auf "Standard", dann auf "Adjust" klicken, dann das notwendige Profil auswählen und laden ("Load") Das gängige Profil "Standard" hat die Einstellungen:    Die Zellen werden automatisch fokussiert, danach müssen Zellen mit hellem Kern sichtbar sein (Capture Bildschirm) <b>Einstellungen anpassen:</b> Helligkeit optimieren ("Light source" verschieben auf $\pm 10$ ) Evtl. solange manuell nachfokussieren bis Ringe zu sehen sind ("Focus" Button drücken und mit dem Slider verschieben), in der Regel liegt der Fokus bei ca. 2900 $\pm$ ; wenn nötig, auch den Zoom hinzuziehen ("Zoom" Button drücken und mit Slider zoomen und nochmals fokussieren) <b>"Capture"</b> drücken, das Ergebnis wird angezeigt; Total Concentration beinhaltet schon die 1:2 Verdünnung Durch kurzes Drücken des Slides wird er automatisch ausgeworfen   korrekter Fokus   inkorrekter Fokus
Berechnen	Angegebene Zellzahl des Counters berechnen: <i>T:\ext01\MED5-LaborWeinhold\Formel zum Berechnen der Gesamtzellzahl</i> Counter: $\text{Zellzahl} * \text{ml} * (\text{falls verdünnt Faktor})$ (bei höherer Verdünnung z.B. 1:10, x 5; bei 1:50 x 25 etc.)
	Danach für RoboSep weiterverfahren nach SOP zum Sortieren der KM-Proben ab Punkt 3
	Neues Profil laden/ändern bzw. Troubleshooting siehe Benutzerhandbuch <i>T:\ext01\MED5-LaborWeinhold\ACHTUNG_LaborOrganisation\Geräte\Manuals_Geräte\countess_II_man</i>

	<b>Cytospin</b>	SOP zur Erstellung von Präparaten für die Zytogenetische Analyse von Myelomzellen
---	-----------------	---

## 1. CYTOSPIN

Schritt	Protokoll	Check
1	Blaue Fertigobjektträger beschriften: Studie, Studien-Nummer / P-Nummer / Datum auf die Hälfte des Beschriftungsfelds	
2	Aliquotieren der entsprechenden Menge Positivfraktion zum Erstellen der entsprechenden Anzahl an Spots mit jeweiligen Zellen pro Spot:  <b>Studien-SOP für die Anzahl der Zellen pro Spot</b>	
3	zentrifugiere diese 5min bei <b>1.500rcf/g</b> in einem <b>2ml</b> Eppi.	
4	Überstand abnehmen	
5	Zellpellet in 100µL/Spot kaltem 1xPBS, ohne EDTA lösen	
6	Filter der Doppelfunnels mit 1xPBS, ohne EDTA anfeuchten	
7	Blaue Fertigobjektträger in die Doppelfunnels einspannen und in die Zentrifuge setzen	
8	100µl Zellsuspension pro Funnel-Kammer an die Trennwand pipettieren (2x pro Doppelfunnel)	
9	<b>6min bei 600rpm</b> (Beschleunigung high) zentrifugieren	
10	Objektträger entnehmen und 5-10min im Abzug trocknen lassen	
11	10 Minuten fixieren ( <b>Methanol-Eisessig Lösung 4:1</b> [90ml 100% <b>Methanol</b> + 30ml Eisessig], ABZUG!) <b>Methanol-Eisessig Lösung 4:1</b> wiederverwendbar, bei -20°C lagern	
12	Objektträger entnehmen und trocknen lassen (ABZUG!)	
13	Qualität der Spots mikroskopisch prüfen	
14	Objektträger bei -20°C für eine Nacht/übers Wochenende lagern	
15	Übergabe an die Humangenetik: 1. Slides 2. Überweisungsschein mit P-Nummer 3. Laufzettel der Studie mit P-Nummer und Reinheit (so bekannt)	

	File:	<a href="#">SOP_CYTOSPIN_06_2021</a>	O:\Med_5\MolBio_Huhn_Reichert\SOPs\SOP_CYTOSPIN_06_2021.docx		Seite 1 von 1

Aktuell gültige Versionen sind  
laminiert.

Schritt	Check
1	Reagenzien 30 min auf Raumtemperatur equilibrieren lassen
2	Agilent TapeStation Controller Software starten
3	D1000 ScreenTape anschnippen und in die TapeStation stellen Barcode auf der Rückseite, unten
4	Benötigte Positionen in der TapeStation Controller Software markieren
5	Benötigtes Material wird angezeigt (Spitzen, weitere ScreenTapes)
6	Reagenzien und Proben vortexen + Spin down
7	Vorbereitung der DNA Leiter:
8	<ul style="list-style-type: none"> <li>• 1 ScreenTape: 3 µL D1000 Sample Buffer (●) und 1 µL D1000 Ladder (●) in Position A1 eines PCR Streifens pipettieren</li> <li>• 2 ScreenTapes: 6 µL D1000 Sample Buffer (●) und 2 µL D1000 Ladder (●) in Position A1 eines PCR Streifens pipettieren</li> <li>• Mehr als 2 ScreenTapes: 15 µL D1000 Sample Buffer (●) und 5 µL D1000 Ladder (●) in Position A1 eines PCR Streifens pipettieren</li> </ul>
9	Je Probe 3µl D1000 Sample Buffer (●) vorlegen und 1 µL DNA dazu geben
10	PCR Streifen/ Platten (mit Folie) verschließen
11	Mischen → IKA MS3 - Vortexer bei 2000 rpm für 1 min (Timer voreingestellt)
12	Proben und Leiter 1 min zentrifugieren
13	Proben in TapeStation stellen Leiter in Position A1 des PCR Streifens
14	Deckel entfernen, sicherstellen, dass die Proben am Boden des Tubes sind
15	Start drücken
16	Ende der Analyse abwarten. ~ 1min je Probe TapeStation Analysis Software öffnet sich automatisch und zeigt Ergebnisse an

Version 3.0	Geprüft am	Geprüft durch	Freigegeben am 08.06.2021	Freigegeben durch: Dr. Stefanie Huhn	Seite 1/2
-------------	------------	---------------	---------------------------	--------------------------------------	-----------

2. genomische DNA

Schritt	Check
1	Reagenzien 30 min auf Raumtemperatur equilibrieren lassen
2	Agilent TapeStation Controller Software starten
3	Genomic ScreenTape anschnippen und in die TapeStation stellen Barcode auf der Rückseite, unten
4	Benötigte Positionen in der TapeStation Controller Software markieren
5	Benötigtes Material wird angezeigt (Spitzen, weitere ScreenTapes)
6	Reagenzien und Proben vortexen + Spin down
7	Vorbereitung der DNA Leiter:
8	<ul style="list-style-type: none"> <li>• 1 -2 ScreenTapes: 10 µL Genomic DNA Sample Buffer (●) und 1 µL Genomic DNA Ladder (●) in Position A1 eines PCR Streifens pipettieren.</li> <li>• Für mehr als 2 ScreenTapes: 20 µL Genomic DNA Sample Buffer (●) und 2 µL Genomic DNA Ladder (●) in Position A1 eines PCR Streifens pipettieren.</li> </ul>
9	Je Probe 10 µL Genomic DNA Sample Buffer (●) vorlegen und 1 µL DNA dazu geben
10	PCR Streifen/ Platten (mit Folie) verschließen
11	Durch Anschneiden mischen (nicht Vortexen → Scherkräfte!)
12	Proben und Leiter 1 min zentrifugieren
13	Proben in TapeStation stellen Leiter in Position A1 des PCR Streifens
14	Deckel entfernen, sicherstellen, dass die Proben am Boden des Tubes sind
15	Start drücken
16	Ende der Analyse abwarten. ~ 1min je Probe TapeStation Analysis Software öffnet sich automatisch und zeigt Ergebnisse an

**Supplementary Information Figure 12. Sequence alignment of IGLV2-14 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences.** N- and C-terminal sequence regions that were excluded in the analysis are highlighted in grey. Bold = reference sequences, underlined = CDR regions, red highlight = discrepancy between the VBase2 and Ensembl IGLV2-14 reference, red letter = mutation, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant.

**Supplementary Information Table 4. Overview of the amino acid percentage of IGLV2-14 assigned AL amyloidosis and multiple myeloma light chain sequences.** MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant.

**Supplementary Information Figure 14. Sequence comparison between MM120 IGLV3-1 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.** For the sequence generated by the Sanger sequencing approach only dominant signals were used. \* = nucleotide position consistent, MM = multiple myeloma patient, NGS = light chain sequence generated through next-generation sequencing, Sanger = light chain sequence generated through Sanger sequencing. Sequencing was performed using the VLKL3\_I\_fw\_NB and CLKL\_A\_rv\_NB oligonucleotides. In the bioinformatic analysis of the bulk RNA sequencing, several sequence sections were given – indicated by NGS\_A, NGS\_B, and NGS\_C. Nucleotide signal overlaps in the Sanger sequencing were specified according to the IUPAC code. The fourth sequence section is not shown as it shows only partial sequence overlap with the CDR3 region, but cannot be completely aligned.

**Supplementary Information Figure 15. Sequence alignment of IGLV3-1 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences.** N- and C-terminal sequence regions that were excluded in the analysis are highlightet in grey. Bold = reference sequences, underlined = CDR regions, red letter = mutation, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant, FOR132 was neglected in the analysis.

**Supplementary Information Table 5. Overview absolute the amino acid percentage of IGLV3-1 assigned AL amyloidosis and multiple myeloma light chain sequences.**

MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant.

**Supplementary Information Figure 23. Sequence comparison of the FOR113, FOR136, FOR163 and FOR169 sequences with the highest percentage in the N\_NGS\_PCR approach and corresponding sequences in the MP\_NGS\_PCR approach.** \* = matching position, NGS\_PCR\_MP = sequence generated by the next-generation sequencing approach based on multiplex forward oligonucleotides, NGS\_PCR\_N = sequence generated by the next-generation sequencing approach based on the VLKL3\_A\_fw\_NB forward oligonucleotide, next-generation sequencing sequences were designated in descending alphabetical order based on the percentage.

**Supplementary Information Figure 24. Sequence alignment of IGLV3-21 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences.** N- and C-terminal sequence regions that were excluded in the analysis are highlighted in grey. Bold = reference sequences, underlined = CDR regions, red highlight = discrepancy between the VBase2 and Ensembl IGLV3-21 reference, red letter = mutation, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement.

## Appendix Results: IGLV6-57 and IGLV2-23

**Supplementary Information Figure 31. Sequence alignment of IGLV2-23 assigned multiple myeloma amino acid light chain sequences.** N- and C-terminal sequence regions that were excluded in the analysis are highlightet in grey. Bold = reference sequences, underlined = CDR regions, red letter = mutation, X and grey highlight = not unambiguously determined amino acid, green letter = linker region, MM = multiple myeloma patient.

**Supplementary Information Table 6. Overview absolute the amino acid percentage of IGLV6-57 assigned AL amyloidosis and multiple myeloma light chain sequences.**

MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement, \_HK = AL amyloidosis patient with dominant heart and kidney involvement, \_HTX = AL amyloidosis patient who received a heart transplant. For comparison, the median amino acid percentage of all detected IGLJ-IGLC combinations and the VBase2 IGLV6-57 reference sequence was calculated.

**Supplementary Information Figure 35. Sequence comparison between MM104 IGLV1-40 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.** For the sequence generated by the Sanger sequencing approach only dominant signals were used. \* = nucleotide position consistent, MM = multiple myeloma patient, NGS = light chain sequence generated through next-generation sequencing, Sanger = light chain sequence generated through Sanger sequencing. Sequencing was performed using the VLKL12a\_Huhn and CLKL\_A\_rv\_NB oligonucleotides. In the bioinformatic analysis of the bulk RNA sequencing, several sequence sections were given – indicated by \_A and \_B.

**Supplementary Information Figure 41. Sequence alignment of IGLV1-44 assigned AL amyloidosis and multiple myeloma amino acid light chain sequences.** Bold = reference sequences, underlined = CDR regions, red letter = mutation, green letter = linker region, MM = multiple myeloma patient, \_H = AL amyloidosis patient with dominant heart involvement. In the bioinformatic analysis of the bulk RNA sequencing, several sequence sections were given – section A is framed. The sequence with the second highest percentage in the overall analysis was used for alignment and analysis of the IGLV1-44 multiple myeloma sequences (sequence\_B).

**Supplementary Information Figure 51. Sequence comparison between MM127 IGLV2-11 assigned light chain sequences generated through a next-generation sequencing and Sanger sequencing approach.** For the sequence generated by the Sanger sequencing approach only dominant signals were used. \* = nucleotide position consistent, MM = multiple myeloma patient, NGS = light chain sequence generated through next-generation sequencing, Sanger = light chain sequence generated through a Sanger sequencing approach. Sequencing was performed using the VLKL12a\_Huhn and CLKL\_A\_rv\_NB oligonucleotides.

```

**Supplementary Information Figure 60. Sequence alignment of the IGLV8-61 assigned FOR229 AL amyloidosis cDNA light chain sequence.** Bold = reference sequences, underlined = CDR regions, red letter = mutation, \_HK = AL amyloidosis patient with dominant heart and kidney involvement. Nucleotide signal overlaps in the Sanger sequencing were specified according to the IUPAC code.

## Curriculum Vitae

### *Personal Details*

Surname and forename	Berghaus, Natalie
Date of birth	24.11.1994
Place of birth	Wiesbaden, Germany
Nationality	German

### *School History*

Secondary school: Max-Planck-Schule, Rüsselsheim  
 Secondary school: Fürst-Johann-Ludwig Schule, Hadamar  
 Abitur: Fürst-Johann-Ludwig Schule, Hadamar (12.06.2013)

### *Academic History*

since 12.2022	Scientific Employee University Hospital Heidelberg Department of Neuropathology, Prof. Dr. Andreas von Deimling Section of Molecular Neuropathology, Prof. Dr. Dr. Felix Sahn
since 09.2019	PhD Position Dr. sc. hum. University Hospital Heidelberg – supervisor: Prof. Stefan O. Schönland “Biological and clinical impact of the immunoglobulin light chain sequence diversity in patients with dominant heart AL amyloidosis”
10.2016 – 04.2019	Master Molecular Biology – grade: 1.5 Goethe University Frankfurt am Main – supervisor: Prof. Helge Bode “Investigation of the Fabelavine-Biosynthesis”
10.2013 – 08.2016	Bachelor Biology – grade: 1.9 Goethe University Frankfurt am Main – supervisor: Prof. Volker Müller “Investigation on the acetaldehyde-metabolism of the acetogenic bacterium <i>Acetobacterium woodii</i> ”

### *Experiences and Awards*

2022	- oral presentation at the “International symposium on Amyloidosis” - DGAK Young Investigator Award
2020	- successful grant application as lead proposer (Stiftungsmittel Universitätsklinikum Heidelberg; 4000 €)
2018	- poster presentation at the VAAM Workshop: “Biology of bacteria producing natural products”

## Danksagung

Zu aller erst möchte ich mich bei allen Patienten und Patientinnen bedanken!

Ich möchte mich bei Prof. Dr. Stefan Schönland, Prof. Dr. Ute Hegenbart und Dr. Stefanie Huhn für die Überlassung des Themas bedanken. Ich möchte mich auch bei ihnen dafür bedanken, dass sie immer hilfsbereit waren und mich unterstützt haben – trotz ihrer hohen Belastung in Klinik und Forschung. Ich habe den größten Respekt vor ihnen.

Herrn Prof. Dr. Stefan Schönland möchte ich darüber hinaus dafür danken, dass er sich die Zeit genommen hat, mit mir meine Forschung zu diskutieren und mich immer gefördert und gefordert hat. Sein Bestreben, diese Erkrankung weiter zu erforschen und schlussendlich ihre Ursache aufzuklären, hat mich sehr beeindruckt. Frau Prof. Dr. Ute Hegenbart möchte ich herzlichst für die Beantwortung aller fachlichen Fragen danken und bewundere sie sehr für ihre Hingabe ihren Patienten und Patientinnen gegenüber. Ich möchte mich auch dafür bedanken, dass sie trotz ihrer hohen Arbeitsbelastung immer ein Lächeln oder ein nettes Wort übrighatte. Ebenso möchte ich Frau Dr. Stefanie Huhn dafür danken, dass sie immer hinter mir stand, sich meine Ideen angehört hat und mit mir daran gearbeitet hat, sie umzusetzen. Ich möchte mich auch dafür bedanken, dass sie mir zugehört hat und wir immer eine offene Kommunikation führen konnten.

Natürlich möchte ich mich auch bei dem ganzen Molekularbiologischen Labor bedanken, für das zusammensitzen, lachen und dafür, dass sie immer ein offenes Ohr hatten. Bei Dr. Philipp Reichert möchte ich mich dafür bedanken, dass er immer sofort zur Stelle war und versucht hat bei allen Problemen und Herausforderungen zu helfen.

Im Besonderen möchte ich meiner Kollegin Sarah Schreiner danken, für alle gemeinsam durchlebten Höhen und Tiefen, in denen wir es geschafft haben, immer aufeinander Rücksicht zu nehmen und uns gegenseitig zu unterstützen. Wir waren immer Mitarbeiterinnen des Monats, haben uns mehr gesehen als jede andere Person und alles geteilt von Gefühlen über ein Zimmer bis hin zu Wein. Wir haben das zusammen durchgestanden und das werde ich nie vergessen.

Ich möchte auch all meinen Freunden danken und im Besondern Gina, da sie die Geduld hatte, diese Arbeit zu lesen und alle meine Kommafehler und sprachlichen Irrwege zu korrigieren.

Besonderer Dank gilt meinen Eltern, die mich immer bedingungslos unterstützt haben und mir ermöglicht haben, meiner Leidenschaft für die Biologie nachzugehen. Ich möchte mich auch bei Philippe bedanken, für das Zuhören, den Versuch zu verstehen, an was ich forsche, seine Wertschätzung und Liebe.

## Eidesstattliche Versicherung

1. Bei der eingereichten Dissertation zu dem Thema

**„Biological and clinical impact of the immunoglobulin light chain sequence diversity in patients with dominant heart AL amyloidosis“**

handelt es sich um meine eigenständig erbrachte Leistung.

2. Ich habe nur die angegebenen Quellen und Hilfsmittel benutzt und mich keiner unzulässigen Hilfe Dritter bedient. Insbesondere habe ich wörtlich oder sinngemäß aus anderen Werken übernommene Inhalte als solche kenntlich gemacht.
3. Die Arbeit oder Teile davon habe ich bislang nicht an einer Hochschule des In- oder Auslands als Bestandteil einer Prüfungs- oder Qualifikationsleistung vorgelegt.
4. Die Richtigkeit der vorstehenden Erklärungen bestätige ich.
5. Die Bedeutung der eidesstattlichen Versicherung und die strafrechtlichen Folgen einer unrichtigen oder unvollständigen eidesstattlichen Versicherung sind mir bekannt. Ich versichere an Eides statt, dass ich nach bestem Wissen die reine Wahrheit erkläre und nichts verschwiegen habe.
